Yes, I change to an LCD monitor and all my noise problems went
away.... Now I can listen on my receiver and turn the monitor on and
off and detect no change in noise lever. Prior to that my VGA monitor
produced about 20 Db of noise.

Outside of the higher price it is a good solution.

If you are puching some device into non-linear operation than reducing
gain helps. Hopefully the filters remain linear.

>He inverts the bandpass curve and calls it an attenuation curve. which it
>is. then draws the conclusion that any signal below the curve totally goes

Of course that isn't true.

>If I understand his writings, he infers that:

Bandwidth does change with amplitude, but not the way I think you are
implying he says it does.

>2. There is a threshold below which no signal gets through. He shows this in
>the shaded areas. This is possible with DSP but I don't think you'll see it
>in conventional mechanical or crystal filters.

Not unless you put the signal into noise floor, or gate it somehow.
Maybe he means it goes below the threshold of hearing??

There is a very interesting pair of articles from Ham Radio Magzine,
February and March 1980, entitled "A New Class of Coaxial-Line Transformers",
by George Badger, W6TC. He uses loops of coax in a choke-like way, but also
uses paralleled sections of coax to create 4:1 and 1:4 baluns. His
measurements show that they compare favorably with core baluns.
Perhaps someone more knowledgable than I who has these in his/her library
can comment.

Dan, KB1RT

Hi

I'm helping a buddy work with an Analog Devices AD 9850BSR DDS chip.
He's trying to use the bit banger method to program the rascal and is not having much luck. Any of you mates had luck with the chip either bit banger or parallel load? I put the chip on an Aires adaptor header for him with a hot air smt unit so I'm pretty sure the chip survived the soldering process. He is a pretty savy programmer and is using an Atmel 51 core controller to manipulate the AD 9850 chip. But so far not peep out of the DDS chip. Any hints would be appreciated.

Source record: 54119

Tom,

Good to hear from you again and thanks for your comments. I was hoping you would come out of the woodwork and add some intelligence to the posting.

To your comments...

If you operate a filter in the linear range...which you must to minimize amplitude distortion...the frequency response must be the same at say -30 dB as it will be at -10 dB. If you put two signals in at the same amplitude with one in the center of the passband and the other on the slope, they will come out at different levels. Drop the inputs 20 dB and they will come out with the same relative levels, only 20 dB down. The bandwidth is not wider for input signals at -30 dB than it is at -10dB. Larry seems to think it is.

As for the threshold of hearing, he suggests turning up the AF gain to hear the wanted signal. When you do, the unwanted signal comes right up with the desired signal. This is linear stuff... you know!

As for the signals disappearing in the shaded areas of the curves, the lower signals are well above the noise level which he has drawn in below. The shaded area somehow performs magic... or is the whole thing smoke and mirrors? Tell us enough times, with enough words and pictures, on enough pages, in enough issues and it starts be convincing.

I e-mailed Ed Hare, W1RFI about the first article the first of February. After waiting almost a month, I contacted Steve Ford, WB8IMY, QST Managing Editor and he prompted Ed to reply. Ed's response was that he had looked over the article and didn't see any problems with it. He said I could sent QST a technical response with my ideas, if I wanted to do so.

As a ham of forty something years and some time in grade as an RF engineering design manager, I hate to see this type of thing printed in such detail and with so many errors, go unanswered. Like J. R. Ewing from the TV program Dallas said, "Once you give up integrity, the rest is a piece of cake!"

Got any ideas?

From: Kerry Whittle <kk7jo@arrl.net>
Message-ID: <3AAEE71D.3060507@arrl.net>
Source record: 54120

Jim,

I had an Icom IC-211 that had problems with keeping itself on the frequency that I desired. The symptoms were different since mine got to the point where it wouldn't tune frequencies away from the default frequency that comes up after the radio comes up after having no power supplied. It started out where the rig would come up like that every now and then or go off freq unexpectedly. I wound up trying to solder teh connections in the VFO to fix it. It seemed to work for a while until I decided to pull the whole metal box out so that I could really do a good job. That was the whole idea until I broke off one of the coax cables that went into the VCO box.

I never seemed to be able to recover from that. It seems that there were many different versions of that model. I also understand that there are very few people that have a good hold on fixing them. At this point I have to ask: do you have the original manual that came with it? If not, everything from here on is a crap shoot with that radio unless you can find the docs or a set of alignment instructions for that radio EXACTLY. I wound up chasing quite a few wild geese before I gave up and wen to the Radio Archives (not sure of the whole name) place that sells documents for old radios. They had something, but it was far from sure being the correct documents. Heck, even the internal placement and the shape of the VCO changed dramatically from model to model.

I hate to tell you all of this, then again if you have the original docs, this could help and it might save you some cash seeking out more docs that aren't available as far as I know unless from a desperate plea posted in newsgroups.

73 es gud luk,

Kerry de kk7jo

Maybe i'm lucky ...
I use to borrow several types of laptops (from 'no name" to
"brand name") and did not observe any kind of RFI to my
RCVR.
All the times I using an old 286 laptop for PR also without
any problem.
Seems to be cheapest to buy an old brand name 386 or 486
laptop (prices up to 150$) for ham use then try to shield new
desktop PC.
Also, my kids are not happy with those old PCs, they're
prefer new ones.

These articles are what first got me interested in "air core" coaxial choke baluns. As I learned more about baluns, I saw that Badger's designs were classical voltage baluns, and that voltage baluns weren't the best kind to use for antennas. (See "Baluns: What They Do and How They Do It" in the ARRL Antenna Compendium, Vol. 1.) The designs work better for antenna use if you remove the third ("tertiary") winding, converting them to current baluns.

Hello Harvey
As for RF Gain down and AF Gain up, they taught us to do this in Navy schools. Old time Military ops do this routinely. I suspect the stuff is linear as far as amplification of noise and signal, however this doesn't take into account the human ear. I find it much easier to copy weak signals using this method with earphones and have taught numerous others to do the same . All have noted a marked improvement. The human ear/mind has a way as acting as a filter (Tuning out your Mother-in-law while watching TV). I wonder if there has been any studies on this. True enough my observations are subjective - but so then is human hearing. I can hear two signals on a frequency and discern either one while partially ignoring the other and lowering the receiver gain helps considerably. The audio gain is only advanced to the point where one can perceive the intelligence.

Would be interested if others have experienced this.

The problem with this is that if a strong sig suddenly appears, it can destroy your eardrums. It is always good to have an AGC circuit that ignores the weaker sig (RF Gain down, Audio Gain up) but catches and restrains the strong sig.

Interesting Bill as most of the DXers and contesters I know emphatically use no AGC or Fast AGC. With receiver gain down and audio up, I have never heard an interloping signal that would "destroy your
eardrums". As I said the audio gain is turned up just to the point of intelligibility and an interloper can be loud but with RF gain down, no way near busted ear drum level.

True enough for rag chewing you probably want medium to slow AGC, but not for DXing on weak signals. In contesting with Med to slow AGC a strong interloper will decrease rx gain so severely as to render the weak signal inaudible, not so with no or fast AGC from my experience.

You ear may vary -- hi hi.

As a DX and Contest guy with 55 years of experience, my personal experience is different than yours. My practice, since the early 1960's, is to adjust RF gain until the AGC is inoperative and set the audio as required. When the strong sig appears, as is *very* common in a contest, the AGC saves the eardrums. It gives time to readjust the controls, if necessary. If you have the July 1963 QST you will see an article that I wrote regarding this subject.

AGC for CW is very common.

The design problem is to have an AGC threshold that remains constant, so that it overrides the RF gain control at any setting of the RF gain control. This, plus the audio gain setting, minimizes the amount of knob twisting.

AGC design has been an interesting subject for many years.

Ah very good Bill, your statement of "My practice, since the early 1960's, is to adjust RF gain
until the AGC is inoperative and set the audio as required".
Is what many of us have been doing for years, perhaps without realizing the "AGC inoperative"
part. Thanks for that insight.

In the Navy we operated CW circuits without AGC, riding the RF Gain and AF Gain controls. But
of course we had clear channels. So I would agree that Fast AGC is in order for contesting. For
weak signal DXing on a closing band, I still use no AGC, don't want an interloper reducing my
receiver gain, so I'll tolerate any interlopers, usually can hear both the DX and the
interloper with no AGC and its the weak DX I'm after.

Thanks for the discussion

Bill,

Thanks for your thoughts on AGC, RF gain, etc...

The origianl question was, "Is the QST Receiver Selectivity Article Correct?" Have you read the two part article by Larry? If so, do you agree with his analysis of how filters work in Kenwood radios? If so, please explain it to us. It doesn't match what I have seen, tested, designed, built and fiddled with for forty something years. {;>)

I skimmed those articles, but did not study them closely. I was somewhat bothered by them because some of the diagrams did not ring my chimes too well, but I cannot be critical because I did not give them the close attention that they require.

Then you need to operate from here and use my receivers!

That is a major problem, and I do EXACTLY what Bill suggests to
eliminate the problem . I allow the AGC to run, but reduce gain until
the AGC is not activated .

I also have added an audio limiter, so the maximum voltage to the
headsets is clamped a a level that won't damage my hearing.

I don't doubt, with some receivers, stages in the receivers clamp or
limit and serve the same purpose.

>True enough for rag chewing you probably want medium to slow AGC, but not for DXing on
>weak signals. In contesting with Med to slow AGC a strong interloper will decrease rx
>gain so severely as to render the weak signal inaudible, not so with no or fast AGC
>from my experience.

I always use AGC, and almost always use full gain and let the AGC work
when working weak signals. It's actually only when the signal is above
an annoying noise (or QRM), that I limit gain.

The only condition where I do not use AGC is when there is severe QRN,
and I don't want to lose any bits of the signal beyond the noise. In
that case I also turn the fileters to a wider position, so they
respond faster (ring less).

AGC is so important, I've built entirely new AGC systems for my
primary receivers. I made every effort to make the AGC fast enough to
following the rising edge of the fastest rising signal that can make
it through the filters, and not overshoot or sag.

I can now listen on fast AGC, and hear noise between dots and dashes
of very strong signals. My own transmitter comes out virtually the
same volume as a 1 uV signal. Of course I have slower AGC positions.

I think the reason people avoid using AGC is many receivers have
horrible AGC systems.

Hello everyone.
Kb9YXM here.
I would like to start to build my own antennas for VHF/UHF. To start, I would like to build what might be a strange 6 meter antenna design.
I am trying to build a 6 meter 2 element phased array.
I was hoping someone could send me some idiot proof instructions or direct me to a website that they know fdirst hand might have information on this type of antenna.
The other quesiton is a simple one. When building an antenna, why must one use a gamma match, isnmt it possible just to use a ballun as with a di-pole?

Thanks and73's in advance.

Hello All,
I recently acquired some really inexpensive 900 Mhz Ericsson Mobitex data radios, model C 719/m. Does anybody have any diagrams or info on these. I really just need a schematic for the RF section, which looks wonderful for tinkering. (10w module, separate PLL's MB1501's, and such) Some programming info on these would be wonderful, but what I am looking to do is scrap the control boards, and just use the RF board with a custom controller. Any help would be appreciated.

Thanks for your help,

Hi, Ron -

Autotune systems include a mismatch detector and control circuit. The detector can be a simple VSWR bridge going to a microprocessor which seeks a minimum (standard zero finding algorithms apply). Fancier systems have phase and magnitude detectors which drive the two servo'ed capacitors via the appropriate gain.

The latter approach is used widely in the plasma etching field - where 13.56MHz power is sent to a reactive plasma chamber via a tuning network. Here, the impedance of the load depends on the energy going to the plasma, which depends on the quality of the match. A design which always and quickly finds a stable tuning point is much valued. These designs also don't use pi networks, but L networks since the load is always a low (2 to 25 ohms) and capacitive impedance.

Best of luck with your designs!

Jim Horn, WB9SYN/6

1647. Signal level for S9 on signal meter ?

Hello all
this is probably a question that is asked many times and probably
has about the same number of different answers !!

But here goes ....

In mV emf at the aerial (antenna) socket what is the recognised
standard for an "S9" signal indication ?

Also I am given to believe that each S unit approximately equates
to an increase or decrease in signal by 6db (ie doubling or halving
the emf voltage) at the aerial socket is this correct ?

Any comments or corrections ?

Many thanks Martin

Hi Josh,

In order of likelihood for success:

1. Find a local ham club and see if anyone has a recent used copy they will sell or 'loan' to you. There aren't a lot of changes year to year, so anything in the last 5-10 years will be adequate to get you started.

2. Check around the area for hamfests, computer shows, etc and check out the swap meet areas.

3. Very occasionally they will show up at used book stores or larger used book sales. Ask if they can check with other used book dealers.

4. Even less frequently you will see one at an estate sale or auction. Usually these are burried in a box or pallet of books and can't be purchased individually unless you know one of the auctioneer's helpers.

Good luck,
Bob McConnell

I wouldn't count on any particular value for S9, although some receivers seem to be adjusted to 50 uV.

The S meter in an amateur meter simply shows the AGC voltage, which is a more-or-less logarithmic function of the signal strength. I'm not aware of any manufacturer currently making any attempt to make the AGC truly logarithmic over a wide range, which would be necessary for S units to be a fixed number of dB. Basically, hams are satisfied with a wiggling meter, and simply showing the AGC voltage is adequate to do this.

Here are measurements of my Icom 730 S meter on 40 meters, preamp out:

S1 - 2 1.4 dB
S2 - 3 1.3 dB
S3 - 4 1.6 dB
S4 - 5 2.3 dB
S5 - 6 1.8 dB
S6 - 7 3.2 dB
S7 - 8 3.1 dB
S8 - 9 4.0 dB
S9 - S9+10dB 5.6 dB
S9+10dB - S9+20dB 7.3 dB
S9+20dB - S9+30dB 6.6 dB
S9+30dB - S9+40dB 10.5 dB
S9+40dB - S9+50dB 11.3 dB
S9+50dB - S9+60dB 13.5 dB

If you switched from a dipole to your new antenna and your signal went from S2 to S6 on my rig and you assumed that this was 24 dB (6 dB per S unit), you'd be in error by 14 dB. You'd think your 3 element Yagi had the gain of an array of about 100 elements. (You'd need a boom length of nearly half a mile to get 24 dB of gain from a 20 meter Yagi.) This is probably one reason a lot of people think their antennas have a lot more gain than they really do.

You should regard your S meter only as something that wiggles, and by no means depend on it for even crude estimates of actual signal strength or signal strength change, unless you've calibrated it. To make quantitative measurements or to calibrate an S meter, use a simple step attenuator. You can find the plans in the ARRL Handbook or other source, and build it in an evening.

Now, the question is, why do you continue to see in ARRL publications and other sources that should know better, the assumption that an S unit

is 6 dB? When asked they say something like, "We don't mean the marks on the meter on every receiver sold for the last 50 years that says 'S units'. We mean something else." But we already have an unambiguous, well defined unit called a decibel. What's the need for another unit that people naturally assume means the marks on their S meters -- but isn't?

Couldn't agree more.

fwiw, my measured S-meter (!) readings on my IC746 are:

S1-2 1dB
S2-3 2dB
S3-4 2dB
S4-5 3dB
S5-6 3dB
S6-7 5dB
S7-8 5dB
S8-9 5dB
s9-9+10 10dB
+10-+20 10dB

to nearest dB - checked overall by dropping from S9 to S1 - total
atten is within 1dB of the sum of the increments.

Pre-amp seems to have abt 12dB gain - at least on 17M.

The other day someone gave me an increase in S-points when I put my
TL922 in that suggested it's giving about 100kW out. Hmmm.

6 db is a 4x increase. 1 "S" unit represents a 6db increase (although most
"S" meters are not accurate).

Hello!

I know S-meters are really innacurate but it seems that there is one 'coincidence point' among lots of rigs, in the S-9 marking: 50uV (or -73dBm, which is the voltage I select in my HP-8640B for testing). I have checked this in about 25 rigs, both valved and solid state and, to my surprise, most of them are very close to a '9' with the test signal at -73dBm.

Just my 0.02 Euro worth ;-)

The 64uv/50uv works out to 2.14 db, which would be just over 1/3 s unit,
if the 6db/s unit figure is right. Given how much space 1/3 s unit
occupies on the scale, that doesn't seem too awfully far off.

That's a really good question, especially given that most receivers are computer controlled. It would seem like almost a trivial exercise to characterize the receiver agc in terms of received signal strength, and then program the results, however non-linear, into the computer's memory, and display an accurate meter reading in terms of db above or below 50 uv, for example. It could even calibrate itself on startup with a few precision resistors switched in and out, feeding itself its own calibration signal.

The S9 Standard at HF is a receiver power input level of 50
picowatts = 50 divided by 10^12 watts.

This corresponds to 50 micro-volts into 50 ohms when the receiver
input resistance is a standard 50 ohms.

A pre-amp should set to 0 dB. Likewise should be an input
attenuator.

Look up the maintenance manual of a modern Icom HF transceiver. No
doubt other reputable manufacturers use the same S-meter
calibration procedure.

It can be deduced from the calibration procedure and examination of
meter scale graduations that 1 S-unit is approx 6 dB. Things may go
awry below S-6 and above S-14. But that's a shortcoming of the
S-meter and receiver AGC - not the Standard.

S-14 = S9 + 30 dB.

Been around for at least 50 years.

Now that we have sound cards and PCs connected to our radios, when will
the autotune routines go after our receivers for optimizations? That
could be pretty cool!

That would only be done if doing so would sell additional units. But I, like the manufacturers, doubt that it would.

Actually, it's unfortunately not that simple. The response is likely to be temperature sensitive, as well as varying with frequency and other parameters. This could all be accounted for or calibrated out (as it is in a good spectrum analyzer, say), but it's just not worthwhile. (Oscilloscopes I was involved with some years ago would recalibrate whenever the internal temperature changed by a few degrees. I'm sure this is common now in a variety of test equipment.) And there's another problem. Judging by the meter, the AGC range of my Icom is around 74 dB. So instead of a meter marked S1 to S9 + 60 dB, it'd only go from S1 to S9 + 26 dB at 6 dB per unit. Plus, I think if you gave hams a real 6 dB per unit meter, there'd be a lot of complaints about how dead the meter is.

I've been told the Kachina receiver reports direct signal strengths, but I have no idea how accurate it is.

The proponents of the S unit seem to fall into two camps. One is the group that assures us that receivers (at least, "properly calibrated" ones) really do indicate 6 dB per S unit. A universal and telling characteristic of this group is that they somehow never get around to actually measuring their S meters. Things are always so much more precise if not sullied by the facts! Then there's the larger group that assures us that it's ok (and for some reason that totally escapes me, desirable) to supplement the traditional dB with an additional unit, a 6 dB "S unit". But, they tell me, it's not really the "S unit" that's marked on the front panel meter of every receiver sold for decades and, don't worry, people know that the "S units" on their meters aren't the same as the 6 dB "S unit" they're so fond of. I suppose if our receiver meters were marked in dB we shouldn't be so presumptuous as to assume that they're really indicating anywhere near real dB.(*)

Roy Lewallen, W7EL

(*) Some time back I suggested to "Kurt Sterba" of WorldRadio that, if he felt a compelling need for a 6 dB unit of measure, he should call it something other than an "S unit", to avoid confusion with the marks on receiver meters. I offered the idea of calling this unit the "Sterby". After his usual one-sided derision and selective quotation of what I had written, he actually did use "Sterbys" ("Sterbies"?) for one issue or so. But then he went back to S units.

Probably the best place to start would be with a copy of the ARRL
Antenna Book. You might also want to pick up a copy of some of the
Antenna Compendiums.

The reason a gamma match is used instead of a simple balun is that
the load presented by the active element(s) in a parasitic array may
not present a known, pure resistive value. A balun only transforms
the impedance, since it's basically a transformer. If the active
element presents a reactive component, the balun will transform that,
too, but it will still be present as a reactive component. Plus,
unless you know the exact impedance value, you won't know what the
turns ratio on a transformer type balun should be. And, since it's
generally hard to adjust the turns ratio on a balun, it could be
difficult to get the antenna matched to the transmission line.
Finally, as you're developing the antenna, the feed point impedance
can vary wildly as you reposition reflector or director (or active)
elements slightly. The gamma match allows you to match both the
resistive and reactive elements of the impedance over a continously
variable range.

Or, something like that. :*)

Note that there are other matching techniques besides the gamma match.
However, for VHF or UHF antenna systems, few are as easy to construct
as the gamma match.

This is one of those 'how long is a piece of string' questions.
There is no real standard for S-meter calibration. The most
commonly accepted convention is: 50 microvolts into 50 Ohms
for S 9 and 6dB per S unit. No doubt others will disagree.

Note: this was cross-posted to many groups. Followup set to: r.r.a.homebrew

I can see that what you're saying about temperature and stability is true if you're talking about something with real precision; but to get better than the figures you quoted, it would be pretty easy, I think- start with a cmos 5 volt square wave, maybe straight out of the vco, put it through an attenuator consisting of resistors switched by 4066's (I haven't fooled with this stuff for about 15 years; there's probably better stuff by now), and feed it through a calibration relay with good isolation, or a pair of dpdt relay contacts with the center contacts connecting to ground when the calibration is off, to the antenna terminal. The isolation would be improved by setting the attenuation to max and turning off the square wave input to the attenuator. It would at least straighten out the non-linearities in the center of the scales.
As to the manufacturers' motivation, you must be right. It isn't being demanded, and it would be just one more thing they could be held to. In any case, the existing system is probably better than needed- from my admittedly limited listening on the ham bands, people don't like to report worse than 5-9.
But I agree that they should use db's referenced to an absolute standard, and it wouldn't be much of a job to add that feature to a software meter.

>
> Dave
> WA4QAL

Excellent advice from Dave here. A lot of very good reasons to use one type of
feed over another, however, one of the other reasons has to do with the mounting
of the driven element.

As you learn more about building an antenna, you will notice that, on antennas with
gamma matches, the driven element is attached directly to the metal mast. The Gamma
match uses the capacitance of the Gamma element to find and match the feedline to
the driven element. The shield of your coax would be tied to the center of your driven
element and the center conductor would feed the Gamma match element.

On antennas that use a dipole of folded dipole driven element, the feed point of
the driven element must be insulated from the boom. This sometimes causes a
mechanical problem, so a builder opts to use a Gamma match, for ease in construction.
A folded dipole as a driven element will present around 300 ohms of impedance
at it's design frequency so you will need a 4:1 Balun, if you plan to feed the antenna
with 75 or 50 ohm coax. The nice part about a folded dipole, mechanically, is that the
very center can be tied directly to the boom without any ill effects. This helps solve
some of the mechanical problems.

I have a tri-bander beam where the driven element is a trap dipole with the feed point
insulated from the boom. To bring the impedances within reason, a Beta match is used
and the Beta match is fed with a Balun. The Balun allows me to use coax instead of
openwire feedline from the shack. Openwire feedline would be nicer to use, but it's
use would be problematic for me.

Well, just my $0.02.

Different definition of 'tuning', John. The earlier discussion is about finding a adjustable matching network's setting which results in the best match for an unknown load. Tuning a receiver is actually an altogether different process.

If you are receiving AM, the carrier can be recovered via any of a variety of synchronous reception techniques and tuning with as much precision as you want is simple. Phase locked loops work well too.

For CW, a raft of methods are available too. In either case, ignoring spurious signals is the trick, not tuning once the desired signal is identified.

For SSB, automatic tuning is more challenging. With ACSB (amplitude compandored sideband), a pilot carrier makes it easy. For general SSB, I'd lean toward speech compressing algorithms to extract the speech parameters and try to determine the tuning offset from there. Definitely DSP time - which, as you say, a soundcard and software could do. But isn't it a bit of overkill?

A stable receiver local oscillator and backlash free tuning makes manual tuning both easy and satisfying, at least for me. Especially for weak, fading, or partially buried signals. I suspect that automatic tuning will have a way to go to beat the human ear here.

At least that's my guess. More power to anyone working to prove me wrong!!

Hmmm....
I do believe that my 6db assumption is still correct as we are measuring
aerial (antenna) voltage not power.
a 3db increase in power is a doubling in that power level
and a 6db increase in voltage is a doubling in the voltage.
This is rooted deep back in my mind .....
Log10 for power to db conversion use and Log20 for voltage I think.

Must get the text books out again

Anyone ever perform the extended range tx modification on the radio. I opened up my radio and followed the instructions according to those posted on the QRZ website and I am not sure where the diode is that they are talking about. Is it the surface mount component just below the (D16) label or is this diode supposed to be to the left of the label where the white brackets are? Incidentally if there is no component where the brackets are, it came that way!

From URL:
http://www.transera.com/htbasic/tutgpib.html#Bus History

The IEEE-488 bus was developed to connect and control programmable instruments, and to
provide a standard interface for communication between instruments from different sources.
Hewlett-Packard originally developed the interfacing technique, and called it HP-IB. The interface
quickly gained popularity in the computer industry. Because the interface was so versatile, the
IEEE committee renamed it GPIB (General Purpose Interface Bus).

You can use google.com and type in HP-IB the GPIB and gets lots of programming info.

National Instruments (http://www.ni.com) is your friend. Their online documentation will take you all the way from newbie to expert in the IEEE-488 business.

I'd suggest buying a NatInst PCII/IIa or similar card on ebay. I bought one similar to this (http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=563459416) from the same seller, and have been very happy with it. The info on the NI site makes it very easy to get started. They supply free libraries for C/C++ and VB programmers that can talk to any of their cards.

All the commercially made loopsticks I've seen have the secondary next
to but not over or under the primary. The primary is many more turns and
connects to the variable cap. The end of the primary next to the secondary
is usually at RF ground.

marvin rosen wrote:

I bought some SA602s (replacement part) from Future Electronics, in Canada, for around $1.26 each last year. The only catch is that you have to buy them in lots of 50, but at this price, you can't go wrong. Future also stocks the TDA1572, which is the AM receiver on a chip that the AOR-7030 receiver uses as its 2nd IF subsystem.

The Motorola MC145152 parallel programmable synthesizer chip should fill the
bill. I have used this chip in the past, and it isn't too bad. With a
50KHz reference frequency, the phase noise performance should be ok.

1692. Re: Is QST Receiver Selectivity Article correct?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-16 03:27:24 UTC
From: 2w8ji@akorn.net
Message-ID: <3ab1820f.58792008@news.accessunited.com>
Source record: 54032

Hi Harvey,

I read the articles, and here is my take on it.

What really bothers me most is the article makes serious errors when considering the ultimate attenuation of the receiver. Look at the opening article, and the first filter shape (1A).

Now look at 1B, where two 1A filters are cascaded. You can see the attenuation at any point is the same as a single filter. The article repeats that mistake over and over again.

Using the passband tuning to offset the filter does not hurt the skirts or the ultimate attenuation (which is assumed to be a lousy value for a receiver, none of mine have that much blowby), it simply makes the filter narrower. The attenuation is not the sum of filter attenuations, it is always the attenuation of the deepest filter.

If the filter attenuation isn't correctly shown, how much sense can anything make?

The last thing I would want to do if I had strong signals above and below me is to stagger the filters, as is suggested. I'd try to keep them perfectly aligned so I had the best shape factor. If I needed more selectivity, I'd use a narrower group of filters.

The reason staggering of filters works ao well in the diagrams is because the filter's attenuations do not add. Very weird.

As to the attenuator eliminating signals, the text does say the signal "falls into receiver noise", which it claims is better to listen to than the rough noise from the antenna. So while S/N ratio does not improve (if the article claims that I missed that claim), the article claims the receiver noise is less bothersome than antenna noise.

Of course the problem I see with that is the antenna noise may vary, and you would be replacing it with a fixed noise level (from the receiver). Operating this way would certainly, if there was QSB, reduce the average S/N ratio unless you "rode" the attenuation.

Personally, I think it is better to let the AGC ride the attenuation....and not use receiver noise to block external noise and signals. When I want to do that, I switch to SLOW AGC.

Did you find out if the article was reviewed?

Josh,
I would like to emphasize the point that Bob made with #1.
There are many hams around you local area that would be glad
to help you out if you can find a nearby club. They can probably help
you with equipment also, and tips on antennas.
Hopefully, you can find a way of getting to the local
ham meetings in your area. If you don't have a car on campus, I'm sure that
some local ham would be more than willing to provide transportation.
Good luck,
Al

Db is always a power ratio. But if you double the voltage in a constant impedance circuit, you change the power level by 6 db because the power = e squared / z, or four times greater.

Isn't it called the AIB (Agilent Interface Bus) now?

Probably not. Believe it or not, I couldn't remember the name and had to do a
web search to find "Agilent." What a clever marketing move.

I was told that S9 +60 is -12dBm or 56mV

S9 would therefore be -73dBm or 56uV

These are referred to by the ARRL and used by most manufacturers I think !!

Certainly my Yaesu was calibrated at the S9 +60 point for -12dBm

What you need is a HPIB (GPIB) "controller". This is a
computer that speaks HPIB language. Probably the
cheapest you could get would be an HP-85, a desktop
engineering "PC" dating from the early '80s. As others
will tell you, there are also cards and software for the
IBM type PC available.

It's not hard to program. I've used my HP-85 for all
sorts of HPIB stuff over the years ;-)

3dB change in voltage is exactly equal to 3dB change in current and
3dB change in power. That's the way decibels work (thank goodness).

>a 3db increase in power is a doubling in that power level
>and a 6db increase in voltage is a doubling in the voltage.

That's right, power is log10 and voltage or current log20.

There is NO standard for S units, or even for S-9. There are a bunch
of suggestions, but that's all. The suggestion the ARRL makes varies
with frequency.

Most of my receivers, when designed, tried to use about 5dB per S
unit. They have various S-9 calibration points. Very few receivers
attempt to use 6 dB per S unit compred to the one's using 5dB or less.

My dozen or so receivers (Drake R4C's, IC-751A's, Yaesu FT1000D,
Collins 75S and KWM-2, etc) all range from about 1 or less dB per S
unit at S1, to maybe 3 or 5dB per S unit near S-9.

Most are pretty close in the dB area of the scale, or at least in part
of the dB area of the scale. With so much change in antennas and local
noise, it makes little sense to try for any standard.

What I do, when I build something, is calibrate the meter in 5 dB
steps, which is what most manufacturers have always done. I set S-1 at
my noise floor, and the pin at the receiver gain compression point.
Most people who ask for S meter readings are interested in
comparisons, not absolute FS. Absolute signal level would be foolish,
with all the variations in antennas or propagation.

What do I care if I am 50uV, or 200uV? All I care about is my signal
to noise and how I compare to others from my area.

The National Radio Club has a lot of information on loop and loopstick
antennas. Check their site, and order the appropriate information
from them. Their prices are quite low. I needed several of their
pubs and saved enough money by joining NRC to pay for the membership
due to the reduced cost of printed materials to members.

I currently have for sale the following old books about Radio:

"Basic Radio; The Essentials of Electron Tubes and Their Circuits" by J. Barton Hoag, published in 1942 by D. Van Nostrand. The 379 page hardbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. Solid binding. Available for $10 plus $2 postage (book rate within the US).

"Radio Operating Questions and Answers" by J.L. Hornung, 10th edition, published in 1950 by McGraw-Hill. The 588 page hardbound book is in about very good condition. Clean with no page tears or pen marks, and a strong binding. The cloth covers scuffs and wear, but no tears in the cloth. Available for $7 plus $2 postage.

"Radio Fundamentals" by Arthur Lemuel Albert, published in 1948 by McGraw-Hill, first edition. The 595 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Nicely illustrated. Available for $10 plus $2 postage.

Or, all 3 books for $25 post paid. If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks, and best regards.

>
> Using the passband tuning to offset the filter does not hurt the
> skirts or the ultimate attenuation (which is assumed to be a lousy
> value for a receiver, none of mine have that much blowby), it simply
> makes the filter narrower. The attenuation is not the sum of filter
> attenuations, it is always the attenuation of the deepest filter.

If I understand variable bandwidth tuning, and I think I do, both filters must be "good" filters with similar bandwidths and shape factors. Otherwise the filter attenuation curves would be asymetrical when used in the VBT mode. Their attenuations do add up but only when they overlap.

>
> If the filter attenuation isn't correctly shown, how much sense can
> anything make?

Actually none... When you start off with an incorrect basic assumption, any conclusions drawn must be flawed.

>
> The last thing I would want to do if I had strong signals above and
> below me is to stagger the filters, as is suggested. I'd try to keep
> them perfectly aligned so I had the best shape factor. If I needed
> more selectivity, I'd use a narrower group of filters.

That works if you have narrower filters. Larry's argument is, I think, you don't have narrower filters and he wants to make what you have work better. That's nice, but does it work?

>
> The reason staggering of filters works ao well in the diagrams is
> because the filter's attenuations do not add. Very weird.

>
> As to the attenuator eliminating signals, the text does say the signal

> than the rough noise from the antenna. So while S/N ratio does not
> improve (if the article claims that I missed that claim), the article
> claims the receiver noise is less bothersome than antenna noise.

I don't believe the Figures agree with the text. They may.

>
> Of course the problem I see with that is the antenna noise may vary,
> and you would be replacing it with a fixed noise level (from the
> receiver). Operating this way would certainly, if there was QSB,
> reduce the average S/N ratio unless you "rode" the attenuation.
>
> Personally, I think it is better to let the AGC ride the
> attenuation....and not use receiver noise to block external noise and
> signals. When I want to do that, I switch to SLOW AGC.

As a "phonie", I almost always use slow AGC. I will kick it up to fast AGC
when I really want to strain the brain and bombard the ears to hear someone.

>
> Did you find out if the article was reviewed?

Last night I e-mailed Steve Ford, WB8IMY, QST Managing Editor, and have not
heard back from him yet. I also ask Steve about the protocol for addressing
issues like this with QST/ARRL. I got almost a month's delay and a waveoff
from the ARRL lab folks in earlier correspondence. Ed Hare, W1RFI said he
had looked over the article and didn't see anything wrong with it. And this
is the technical staff...? {;>)

And so it goes, my friend...

Nice synopsis Martin - however I would suggest the RST System as the universally accepted reporting system as it includes CW reports as well. Your definition of S7 may mean little to the other person. But an RST of 57(9) has a definite meaning.

I once made a CW contact and my QSL card came back with a 59 report and the DXAC turned it down as it should have been 599. So QSL cards should give the RST report and indicate the mode of operation 59 for voice, 599 etc for data. So might as well give the other person an RST report not an S-Meter reading or give both, perhaps. S7 ain't necessarily RST 57

Incidentally DXpeditions, contesters, and some DX stations always use "Ur 59" "Ur 599" so they don't have to type in or write in the true report, saves time. A questionable practice but an oft used one.

Then there is the military report of you are 5 by 5 with the last 5 being the highest, confuses everyone on the Ham bands as folks think it is 5 by 5 in the RST system.

FYI for readers

READABILITY
1 -- Unreadable
2 -- Barely readable, occasional words distinguishable
3 -- Readable with considerable difficulty
4 -- Readable with practically no difficulty
5 -- Perfectly readable

SIGNAL STRENGTH
1 -- Faint signals, barely perceptible
2 -- Very weak signals
3 -- Weak signals
4 -- Fair signals
5 -- Fairly good signals
6 -- Good signals
7 -- Moderately strong signals
8 -- Strong signals
9 -- Extremely strong signals

TONE 1 -- Sixty cycle a.c. or less, very rough and broad
2 -- Very rough a.c. , very harsh and broad
3 -- Rough a.c. tone, rectified but not filtered
4 -- Rough note,some trace of filtering
5 -- Filtered rectified a.c.but strongly ripple-modulated

6 -- Filtered tone, definite trace of ripple modulation
7 -- Near pure tone, trace of ripple modulation
8 -- Near perfect tone, slight trace of modulation
9 -- Perfect tone, no trace of ripple or modulation of any kind

Infrequently used is the addition of a letter to the end of the 3 numbers.
These are: X = the signal is rock steady like a crystal controlled signal;
C = the signal is chirpy as the frequency varies slightly with keying;
and K = the signal has key clicks.

X is from the early days of radio when such steady signals were rare.

Today most all signals could be given an X but it is hardly ever used. It is
helpful to report a chirpy or clicky signal
by using the C or K, e.g. 579C or 579K.

In any sort of normal use the filters ALWAYS overlap in some part of
the curve, so the attenuations must always be added in that area.
Since the article never adds the attenuation, everything shown is
incorrect.

OK, so we know the passbands are all incorrect.

>That works if you have narrower filters. Larry's argument is, I think, you
>don't have narrower filters and he wants to make what you have work better.

Not as shown. As I said:
>> The reason staggering of filters works ao well in the diagrams is
>> because the filter's attenuations do not add. Very weird.

Not adding the filter attenuation was a major oversight, since every
conclusion is based on the attenuation.

I also agree the noise thing is misleading. Pushing the noise or QRM
into the receiver noise floor does NOT improve S/N or S/QRM ratio.

True. IEC60315-6 gives the method of measurement of S-meter characteristics but it is not a performance standard and therefore does not define the meanings of S numbers. In spite of this standard being proposed and written (largely) by UK experts, BSI failed to adopt it as BS4054-6.

Hi, I have a Hallicrafters SR-160 that starts to screech/whine when there is little or no receive signal present. The static on 20m is usually enough to prevent the problem, but not always. Does anyone know what may be causing the problem? I've had the rig for 9 years and use it primarily as a reciever. I know I have never changed any of the tubes and I don't know how long they were in before I was given the radio. Thanks!

Being tube based, it probably has a number of grid-leak bias circuits in the received signal path. If the capacitor becomes leaky, the bias won't hold up without a signal, changing the operating point of the tube (and, for many, the gain). Those old capacitors may be the problem.

Best of luck!

Mike,

My guess is you have one or more bad decoupling capacitors in the high voltage line to your RF and/or IF amplifiers stages. With the reduced signal, the AGC allows the gain to go to max and there is enough positive feedback through the high voltage supply line to cause oscillation.

Try temporarily paralling each one of these capacitors with another of equal or larger capacitance and see if the noise goes away. If it does, replace the old capacitor.

Good luck and 73,

Harvey, K5LJM

From: Sam Brutcher <sbrutcher@-->
Message-ID: <SAys6.17$kT2.181@bos-service2.ext.raytheon.com>
Source record: 54013

I'm getting back into homebrewing after an absence of several years. I'm not an engineer. I've been browsing the net looking for projects to build. Several British sites (esp. the G3YCC "tribute" sites) have some QRP gear that looks interesting. I've already figured out that NTE can show me subsitutes for the "BC" type transistors specified in their schematics. What I can't locate is correct part numbers for Toko coils.

The schematics I've found refer to parts such as "BKANK3333R." Toko's web site, however, shows no such part in their inventory. The "G3RJV Data Card" for coils at http://www.btinternet.com/~g4wif/q_tech5.htm provides specs for some commonly-used inductors, but again, none of Toko's current products seem to match in terms of inductance or Q.

Is this a European vs. American or old vs. new part number question? Can anyone tell me if there's a simple way to cross-reference these part numbers? If not, can I safely substitute a 47uH inductor with a Q of 45 for a 45uH inductor with a Q of 60?

Thanks for your help (and patience with a newbie question...)

The only place you can put a volume control in such a circuit is between
the output of the 555 and the speaker.

The too quiet and too loud split is because the trimpot is too large
compared to the impedance of the speaker. Say the speaker is 8 ohms.
If the trimpot is out of the circuit, or at zero resistance, you
of course get maximum volume. If you set the trimpot to 8 ohms, which
would be just a teensy bit from zero resistance, the volume would be
half. Look up voltage dividers in your reference book. But since
it's finicky to get that little resistance, a tiny change of the trimpot
will likely set it to a higher resistance, and then the volume is
way down, and it only gets worse as you adjust the trimpot from
there.

The simple solution is to use a trimpot or pot with a much lower
maximum resistance, like 100 ohms or maybe even less. This
doesn't change the matter of a large resistance giving you no
volume, but it will mean that more of the turn of the trimpot
will be in a range where volume will be affected.

As for the trimpot getting warm, it's because it is being asked
to drop voltage, and that voltage is being dissipated as heat.
You need to use something that can better handle more current (just
as when building, sometimes you need to use large wattage resistors).

You do have a coupling capacitor between the output of the 555 and
the speaker?

>
>Thanks for your help (and patience with a newbie question...)

The BKANK3333R is in the web catalog of the UK distributor, BEC. Go to
http://www.bonex.co.uk/PG800/8var/p25.htm and scroll down the long page
(or use your browser to search the page for the part number).

If you can't get any sense out of TOKO USA, I'm sure that BEC can help -
their main site is www.bec.co.uk and they take small credit-card orders
by phone and fax.

For UK buyers: the old TOKO suppliers, Cirkit, are now out of the retail
components business - BEC is the place to go for TOKO.

May 96 QST featured a technical award winning article on an advanced AGC/IF system by Bill Carver. It included values for a 9Mhz if. Far circuits, which is on the Web at http://www.cl.ais.net/farcir/receiver1.htm , sells circuit boards for the fairly complex circuit.

I'd appreciate hearing from anyone who himself has tried the circuit or might know of someone else who has. I am hoping to adapt it for use in a Ten-Tec Corsair and replace the audio-derived hang agc. [Any other circuit suggestions also gratefully received.]

1726. HTX-400 power source

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-17 14:28:27 UTC
From: AB2HR <ab2hr@arrl.net>
Message-ID: <2es6bt8ufnsjduj8sfcnffmdgf9gv8h5kk@4ax.com>
Source record: 54052

Hi folks... Picked up an HTX-400 440 rig from Radio Shack the other day, couldn't resist as the price was a VERY attractive $70. Anyway, as those of you who are familiar with this product know, it's not a very powerful transmitter but it IS capable of 1 watt output with an "external 9 VDC power source." I had planned on building a 6 cell Alkaline battery holder which I could connect to the radio which would give me the 9 VDC for 1 watt output in "walking around mode." Well, as I was wandering about Radio Shack, I noticed that they sell a 9.6 volt 1000 mAh battery for R/C toys. Immediately I began wondering whether or not this 9.6 VDC power source was compatable with the radio, and if not, what could be done to make it suitable for use with the HTX-400.

The guy behind the counter (at three stores) had no answers. I e-mail the Shack's own tech support. The response was a canned reply stating that they do not offer mods or modification advice on any of their radios (HELLO! I'm talking about building a battery pack here, NOT modifying the radio!). Got nada....

So, here's what I came up with.... at 9 VDC current train at transmit is 900mA (from the manual). at "standby" or receive, current drain seems to be 50 mA (based on QST review of the 2-meter variant, the HTX-200). If I were to simply insert a 12 Ohm resistance (.6v drop at .05 A) to bring the voltage to 9VDC during standby operations, this results in a voltage deficit of 1.2 volts on transmit! (.9 mA * 12 Ohm = 10.8 VDC). By inserting a .67 Ohm resistance the .600 VDC drop is realized on transmit, but at standby I'm pushing 9.57 volts through the unit. Is this acceptable? Would the radio accept 9.6 VDC directly from the battery? Obviously there must be a way of regulating the voltage (yes folks, I think I need to build a voltage regulator) to allow the use of this NiCad battery pack as a power supply for this radio. I'd appreciate any and all information anyone can give me on this.... schematics would be GREATLY appreciated.

Thanks much!

Hi Barry,

It's amazing where manufacturers quit worrying about performance.

I replaced the AGC system in my R4C's with a homebrew AGC that wasn't
fancy at all. I used an emitter follower to drive a transformer that
had a full-wave rectifier system, and then drove a darlington emitter
follower that charged the "hang time" components.

I can't imagine needing something fancier, because this simple system
stays right with the rise time of even the fastest envelope that can
make it through the filters. It also sources enough current to charge
all kinds of bypass capacitors rapidly.

In the Drake, the biggest problem I had was the group delay in the IF
filters and leakage of the BFO into the IF. With 3-8mS group delay, I
could NOT apply normal AGC to stages in front of the narrow filters.
(I do use a little "level delayed" slow-discharge AGC to the RF amp,
it is applied when signals get over 0dBm at the receiver input).

You'll have to watch for odd things like that when making a mod like
this to any receiver.

If you're talking about the difference between running it on 9v. versus
9.6 v., I can't imagine it not being able to sustain that. One of those
external plug-ins that would put out 9v. with one amp would probably run
up quite a bit higher with no load, unless it was regulated. Unless the
htx thingy specifies a close tolerance on its supply voltage, I wouldn't
worry about such a small difference. In fact, if the thing is made to work
with alkaline cells, when new they put out 1.55 volts each, which times

six is 9.3 already.

You'd better check the technical manual for the exact model you own before hand. You never mentioned the brand or model. For example, a Motorola Micor receiver made for the High VHF split (the 160 MHz region) will NOT reach the amateur band unless the helical frontend is replaced. For many other commercial radios you might also have to consider going from low-side to high side LO injection.

Also, most modern VHF transmitters use broadband matching in the predriver, driver and PA stages. Again, the parts are often picked at the factory for the intended VHF split the radio was intended to be used for. A government or railroad 160 MHz set often becomes extremely inefficient when operated in the 2-meter band for these reasons.

So yes, you run the risk of damaging the PA, and your radio may not reach the 2-meter band regardless. There is no quick or easy answer to your question based on the info you/ve provided.

For Sale - TET 433 Yagi Beam
The TET Model 433 specs which are below.

The TET model 433 is a three element beam for 40, 20, 15, and 10 meters. Two driven elements, with two active elements on 40 and three active elements on 20, 15, and 10.

This TET was one of the last ones made just prior to the closing of TET and the death of the owner Mac Taniguchi TET Beams were outstanding in their exceptional bandwidth, construction, and operation. Bought new in August 1988 and still in original box, never assembled.

Selling for $450. Pick up at my home in Houston.

Specs:

Active elements: 40 M - Two
20, 15, 10 M - Three

Gain: 40 M - 2.1 dBd
20 M - 8.2 dBd
15 M - 8.7 dBd
10 M - 7.3 dBd
Bandwidth (1.5:1 SWR) 40 M - over 100 kHz
20 M - over 350 kHz
15 M - over 450 kHz
10 M - over 1 MHz
Element Length 30.5 feet
Boom Length 13.2 feet
Weight 32.1 lbs
Power 1 KW CW (higher SSB)

e-mail me direct off-net please.

The GE is a "DO" cabinet, probably a Progress Line, circa 1965. Junk
it.

The Motorola is a useable radio, but will require substantial mods to
put it in the 440 mHz range. There is something non-standard about it
as indicated by the "X" model prefix. That generally meant "Special
Product built on a production line", as opposed to a suffix of -SPxx
which indicated a "Special Product" built in a small quantity.

Good luck.

The primary coil is the one that you would tune. It should be around 240uH, if you use it with an 18 to 400pF tuning capacitor. You do not need to wrap the secondary over the primary, it can be around 10 turns of Litz wire, wound next to the primary. You should have pretty tight coupling, if you use a ferrite rod.

My guess is that 9.6 volts wouldn't damage anything in the rig but I understand
your want to stick to the specification. However, you have a problem trying to
regulate 9.6 volts down to 9 volts. The differental is just too small for standard
voltage regulators to work properly. They usually need about 2.5 volts differential.
I don't think that even low differential regulators go that low. And as soon as the
battery drains to the point that the differential is insufficient, regulation becomes
poor.

The dropping resistor method is not the way to go. As the battery drains, the
drop is going to change. Depending on the mode, the drain might change while
you are talking. This will change the voltage drop. Also, the 900 ma drain may
be a peak specification. It may nominally be much less. I would first hook up a
9 volt battery and check the actual current drain in all of it's modes, then work from
there. As an example, I have a HTX-100. The manual specifies 13.5 volts at
8 amps for full output. But in SSB mode 8 amps is only necessary on voice peaks.
Most of the time the average speech needs less than half that. I ran the rig on a
3 amp power supply for a long time by just limiting my audio peaks. I have
since upgraded the power supply to an 8 amp one and don't have to worry about
the audio peaks.

But, all of this can be taken care of by using a 12 volt battery instead of a 9.6 volt.
It would then be very straight forward to build a 12 --> 9 volt regulator. Radio
Shack also has some nice 13.5 volt 3 amp hour batteries. A simple LM317 regulator
would easily handle an input of 10.5 to 15 volts and keep the output at 9.0 volts.
The regulator and all the parts can be obtained at Radio Shack. The advantage of
this is that you can then get a cigarette lighter plug and run your rig directly from
a car battery or charge your battery from the car.

A fused lighter plug is also available at Radio Shack. I'm really not on
the payroll of Radio Shack but they do have a lot of useful stuff, if you know what
you are looking for. I built a 8 amp 13.5 volt power supply for my HTX-100 all

from Radio Shack parts. I put it all in a nice case and now have a nice
base rig
for 10 Meters.

Greetings everyone.
I am interested in building a radio receiver that can receive frequency
between 43MHz and 46MHz

1)Where can I find circuits on the web for such a receiver?

2)Will a trimmer capacitor work for this receiver or do I need the
kind of variable (tuning) capacitor that is used in an old radio?

Thanks

Paolo,

The oscillator in the an419 note is only good to about 150 MHz. Above this frequency you will have trouble with it.

You might want to try it running at 300MHz/4 = 75 MHz and then use the 9854's internal multiplier to get to 300 MHz.

The other alternative would be to phase lock a SAW based oscillator at 300 MHz to a lower frequency crystal oscillator. Then you would play with the loop filter in the phase lock to clean up the SAW.

My experience with the 9854 would indicate that you will not see a major improvement in performance using either of these methods.

Bob,
I agree with you, about spurs and PLL solution.
Hands electronics http://www.rf-kits.demon.co.uk/run.htm in UK has a module DDS3A using an AD9851 clocked at 180 MHz and phase locked for high purity applications to a clean up loop available as the GQ-PL9 at about $200.
My question was in order to achieve the maximum phase noise performance, and to have a 300 MHz clean source as in http://www.analog.com/techsupt/application_notes/an419.pdf

If you are talking about tuning the frequency range 43 to 46 mhz, that's only a 7% change, and a trimmer should do it. If you compare that to the broadcast band on an old AM radio, where you go from 550 khz to 1650 khz, that's about a factor of 3, or +300%, which would require a much larger capacitance ratio. On the other hand, it might not be convenient to tune the thing with a screwdriver, so you might use a wide range variable capacitor hooked to the tuned circuit through a series capacitor so that it made only a 7% change to the tuned circuit.

Bob,

thanks for sharing your experiences.
So finally what do you suggest as a better compromise to achieve a minimum spurs level and a maximum performance in terms of phase noise , as your previous reply stated, is to use some kind of VCO, locked to the 9854, if I will use it as a first LO via a PLL chip so I can clock the standard unit (AD9854ASQ or AST?) at a lower frequency.
Wich frequency please?
Discrete or DIP clock?
Are you going to write an article about that on some magazine?
Thanks.

Hello !

Presently, I build an ATV repeater with some friends and we are looking for an antenna horizontally polarized with an omnidirectional radiation pattern. The equipment is going to operate in the 23 cm band and a high gain is obviously highly wishable.

I have seen descriptions of the Alford slot antenna which has a medium gain and would be suitable, but commercial TV stations often use superturnstile antenna which have more gain.

Does someone hear of homebrew superturnstile antenna for the 23 cm ham band or other high gain antenna ?

Thank you for your help.

Look at the selectivity curves Bill, and your chimes will go silent.

The attentuation of cascaded filters is not added correctly
(attenuation is not added at all), so every conclusion through the
whole article based on attenuation amounts (and that's the whole
thing) is wrong.

Ray,
Although I wouldn't worry too much about .6 volts over rating, you can put a diode drop in. The forward drop has a pretty sharp knee, so you might loose 0.55 volts at 50 ma, and 0.65 volts at 1 amp. Although most regulators drop at least a couple of volts, there are some that work on a lot less. They use a pnp series pass transistor, so in theory can regulate to within a drop of 0.2 volts.

I just purchased a couple of these rigs also and had the same thought. My first concern is that although nicads are rated at 1.2 V/cell, they can be as high as 1.4 V/cell when freshly charged, and given a light load. This would be 11.2 volts instead of 9.6, which would concern me. However, I looked over the parts list and noticed a 3V regulator, probably for the microprocessor, and other digital stuff. So I'd say that the brains of the radio are safe.

The next concern would be overloading the
output circuitry. Assuming that the resistance of the load remains the same, the power dissipated increases with the square of the voltage, so a difference of 11.2-9.6=2.2V may be significant. However, a nicad cell, even when fresh would probably drop to 1.2V when generating 800mA, so when you are transmitting, the voltage should drop to near 9.6V and the .6V overvoltage would probably translate to about a 5%-10% increase in power dissipated, wich shouldn't be significant. I doubt their design tolerances were that tight. Anyway, my radios are on order, so I haven't been able to test my theory yet. If you try it, and it works fine, please let me know. Thanks,

Nathan kb9yzf

get a copy of the Radio Amateurs Handbook any issue since the 80s is fine..
your specs need to include sensitvity required, am or fm, selectivity,
stability, etc..
the easiest is to build a converter and use it with an existing receiver..

Source record: 53960

Hi Paolo,

Here's what I would do:

1) Grab what ever crystal you have in the 90 to 120 MHz range, frequency isn't that important. Build an oscillator and use that to clock the 9854. No matter what circuit you use your oscillator will be better than the cheap DIP clocks. I could recommend a brand of oscillator, but then I'd have mention that I'm recommending my employer's parts ....

2) Depending on crystal frequency come out of the DDS at about 1/5th to 1/6th of the crystal frequency. Run the DDS output through a simple bandpass filter, Run the output of the filter into a PLL chip. The National Semiconductor parts seem to work well.

3) Build as good a VCO as you can -or- buy a MiniCircuits part for < $30.

4) Lock the VCO up to the output of the DDS with the PLL chip.

5) Use the DDS in a narrow band mode (say about 10% range). Use the PLL chip for large steps (say 5.0,5.5,6.0,6.6,7.2 etc).

6) Once you have the receiver system running sit down with a good signal generator (or a crystal oscillator) and measure how wide you can make the PLL bandwidth on the National chip before things begin to degrade. With a whole lot of data you could calculate it, but for a one of a kind project measurement makes more sense.

You can play with VCO range and VCO performance. Generally a narrow band VCO will have better characteristics than a wide band VCO. If you are running a 70 MHz IF frequency and trying to cover DC to 30 MHz your VCO would need to cover 70 to 100 MHz. If you split that into four segments then each of them would be about a 10% range (69 to 77, 76 to 84, 83 to 92, 91 to 101 MHz).

One other trick to consider on the VCO - run it at 4x or 8x the desired output frequency and then divide it down with a digital divider chip. This will give you very good load isolation and good power output leveling. With a good divider it should make the spurs and phase noise better.

If the main concern is for the ham bands I'd build a VCO for each band of interest and bandpass filter the VCO before I put it into the mixer. You might even put the whole front end on a card and switch out cards.
Each card would have:

front end preselector(s)
RF preamp or RF attenuator depending on band
first mixer
mixer if termination
LO VCO
VCO divider
VCO bandpass filter

Sounds like a lot, but about the only parts that would be duplicated are the preamp, mixer and attenuator. Each card would connect to power, antenna, IF, and the synthesizer chips.

One other note - there is no reason why you can not run the DDS output from say 14 to 20 MHz and lock up a VCO running from 70 to 100 MHz with a fixed division on the PLL chip. This would make a more simple system and cut out all the VCO switching.

There are a *number* of people lurking around here that know a whole lot more about this than I do. Maybe one of them can write the magazine article :)

Enjoy!

Bob,

thanks for sharing your experiences.
So finally what do you suggest as a better compromise to achieve a minimum spurs level and a maximum performance in terms of phase noise , as your previous reply stated, is to use some kind of VCO, locked to the 9854, if I will use it as a first LO via a PLL chip so I can clock the standard unit (AD9854ASQ or AST?) at a lower frequency.
Wich frequency please?
Discrete or DIP clock?
Are you going to write an article about that on some magazine?
Thanks.

Hi. My name's Josh. As some of you who have seen my previous posts know, I am new to radio design. I am looking to play with what I think is the very fascinating concept of mixers for the first time. I have been studying some schematics I have seen, and noticed a mixer, the NE602, which is used several times in the design of radios by the Wilderness radio company. Is this unit a good one to get ahold of to toy with for learning purposes? And for that matter, when I have two frequencies mixed together, how will I be able to detect each of them at the same time...or will I? (I would guess my scope won't show me the two at once, neither will the freq. counter.) Is this generally the way a transmitter is built...one low freq. is mixed with another to make a higher and higher freq., with alot of filtering in between, until the desired is met?

Thanks for your help

Josh,
You're on the right track. The output of a mixer is going to have
both the sum and difference of the two signals inserted, as well
as remnants of the original freqs. This has to be filtered at the
output.
Various bands in a transmitter (or receiver) are obtained by
various methods...sometimes its a single 'conversion' process,
sometimes more stages are utilized. Typically in a single
conversion receiver, the oscillator range is switched to beat
against the incoming signal, always resulting in a common
Intermediate Frequency. In this case, the IF amplifying stage(s)
serve for the filtering process and all the other freq components
are removed.
From that basic premise, there's zillions of various
configurations as the receiver gets more sophisticated...and of
course, an xmtr often works in the "reverse" fashion.
As for seeing and measuring the freqs, as you rightly suspect, a
counter can't tell you anything. However, with some idea of what
the freqs should be, you can 'find' them on a scope display.

OK, Bill talked about the output, let me talk about the chip.

The NE/SA 602/612 is a good part, and it's not. Like so many things, it all depends.

Recently, the 602 has been hard to get, but you can get them. They are cheap, easy to use, and very sensitive. For most HF applications you can take your antenna through a bandpass filter and straight into the 602 with no amplification. You can simply attach a crystal or LC network to the 602 and use it's internal oscillator. You can build a perfectly useable HF receiver with nothing more than a 602 and an audio amplifier. For learning purposes, it's a great little part.

You will see NE602, SA602 and SA612 parts. For practical purposes, they are all the same.

Basically, there are 2 kinds of mixers in common use, ring diode and Gilbert cell. The Gilbert cell mixers are more complicated internally but easier to apply. The only other Gilbert cell mixer I know of is a 1496 which is a lot messier to use than the 602.

Ring diode mixers are a lot more expensive than the 602, although you can build one from 4 diodes and a couple of ferrite cores. The problem with a diode mixer is that you generally need to provide more amplification going into the mixer, which results in more power consumption. Most of the QRP rigs that use 602's are after the low power consumption because people often run these radios off batteries.

The big downside of the 602 is that it suffers horribly from IMD. Depending on your application this may not be much of a problem, and you can reduce the problem with a good front end filter. For experimentation it's really not much of an issue. Some very fine radios use the 602. Check out the schematics (online) for the SW-40+, the Norcal SMK-1, and the Elecraft K1 for some examples.

hope this helps

[Please, note that this message are being crossposted to
rec.radio.amateur.homebrew and sci.electronics.misc]

I want to build some Return loss bridges for use with my home spectrum
analyzer. For use from ~DC-12GHz(dreaming) in various subbands, to test
homebrew equippment.

The RLB (hibrid combiner) I knew about was the Z0 resistive bridge with 1:1
transformer balun with 0 or 180 deg detector output, that has a 6dB
insertion loss. But recently came across a design that uses a transformer
instead resistors for the upper half of the bridge that intuitively seems
that will save 3dB at the expense of (mainly) the low frequency response.

The simulations in spice I did seems to comfirm this, although was the
ideal case.

What I'm questioning are the tradeoffs between using resistors or a
transformer for the upper half of the bridge, before building a bunch of
both. Also comments about the best way to homebre the higher frequency ones
will be wellcomed.

: I want to build some Return loss bridges for use with my home spectrum
: analyzer. For use from ~DC-12GHz(dreaming) in various subbands, to test
: homebrew equippment.

Hi there,

you would be dreaming to cover that large of a bandwidth in one box. most
of the commercial and better projects limit their ranges to specific
blocks of bandwidth.

: The RLB (hibrid combiner) I knew about was the Z0 resistive bridge with 1:1
: transformer balun with 0 or 180 deg detector output, that has a 6dB
: insertion loss. But recently came across a design that uses a transformer
: instead resistors for the upper half of the bridge that intuitively seems
: that will save 3dB at the expense of (mainly) the low frequency response.

The transformer unit will preform better.

: The simulations in spice I did seems to comfirm this, although was the
: ideal case.

and in reality, I have a few of them myself. Check out Eagle's rlb if
your need some typical specs.

: What I'm questioning are the tradeoffs between using resistors or a
: transformer for the upper half of the bridge, before building a bunch of
: both. Also comments about the best way to homebre the higher frequency ones
: will be wellcomed.
: 73's de Luis

Hi Luis,
I've got a few commercial and amateur versions here for my own use, the
"swrsweep", hp, eagle and a few other oddballs work pretty well. I like
the predictable nature/responce of the transformer units although they
tend to have much more drastic problems near their uppper and lower
frequency limits. I don't have much time to look, but I do have some
circuit diagrams I could share with you if your patient and want to wait
for me to dig them out.
cheers

Hello,

I have some Mullard EL 34 valves for sale. All are unused, original packed, only opened by me for inspection. The have double, round getters on the top and the coding is:

9 pcs Xf2 6703 (I guess they are made in March 1967)
These have one pin missing in the base

1 pcs Xf1 B1K
1 pcs Xf1 B1K4
and these have all their pins.

and so there is one valve that are labeled Siemens, but it is obviously a Mullard valve. It is identical to the others and it has a code: Xf2 B7J4

Please give me an offer by e-mail.

Regards,

Hi
Would anybody help me for selecting a suitable VHF wireless microphone?
Because I am using a SONY WCS 900MHz wireless microphone for voice pickup of the speaker during the meeting or sharing, but the performance is not satisfactory.
It is always interfered with the noises, even the distance between the transmitter and receiver is less than 1.5 meters and I have already tested the performance of three sets of this product, the result are the same. Not satisfactory.

I am now want to source for another set of Wireless Microphone (VHF). Would you please refer to the following working condition and the product information to give me some comments and advises?
Does the power of the transmitter have significant difference for 20mW and 50mW for my application?

Working condition: The maximum distance between transmitter and receiver is under
10 meters. (in Hong Kong)
It may have one or two concrete walls and peoples seperating from
the transmitter and the receiver.
Portability: can use bettery for both transmitter and receiver.

Product 1: SAMSON Camcorder VHF wireless microphone
Transmitter : model VT3L, RF Power,20mW;
Receiver: VM1 Double antenna, Single Conversion Super Heterodyne Diversity (I don't know whether it is true diversity or
phase diversity and the actual performance between these two),
sensitivity: =<6 micro volt @ 20dB S/N

Product 2: SHURE Camcorder VHF wireless microphone
Transmitter : model T1, RF Power,50mW;
Receiver: Non-diversity single antenna,
sensitivity: -109dBm (0.8 micro volt @ 12dB SINAD)

I will not consider buying the following product, because it cannot use bettery for the receiver unit. But do you have any comments for the comparison between product 1 & 3. Since there is only the difference between the Receiver Sensitivities and with the same transmitter unit VT3L; and I had the experience (very good performance, without any noise) in using an OLD model SAMSON VHF wireless microphone which is nearly the same as the product 3.

Product 3: SAMSON VHF wireless microphone
Transmitter : model VT3L, RF Power, 20mW;
Receiver: VR3TD Double antenna, Single Conversion Super
Heterodyne Microprocessor True Diversity
Sensitivity: <3 microvolt for 20dB SINAD, < 10 microvolt
for
50dB S/N

1783. Get help for selecting a VHF wireless microphone

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-21 07:45:25 UTC
From: Joshua Lo <joshualo@vtc.edu.hk>
Message-ID: <999lj3ett1@dragon.vtc.edu.hk>
Source record: 53980

Hi
Would anybody help me for selecting a suitable VHF wireless microphone?
Because I am using a SONY WCS 900MHz wireless microphone for voice pickup of the speaker during the meeting or sharing, but the performance is not satisfactory.
It is always interfered with the noises, even the distance between the transmitter and receiver is less than 1.5 meters and I have already tested the performance of three sets of this product, the result are the same. Not satisfactory.

I am now want to source for another set of Wireless Microphone (VHF). Would you please refer to the following working condition and the product information to give me some comments and advises?
Does the power of the transmitter have significant difference for 20mW and 50mW for my application?

Working condition: The maximum distance between transmitter and receiver is under
10 meters. (in Hong Kong)
It may have one or two concrete walls and peoples seperating from
the transmitter and the receiver.
Portability: can use bettery for both transmitter and receiver.

Product 1: SAMSON Camcorder VHF wireless microphone
Transmitter : model VT3L, RF Power,20mW;
Receiver: VM1 Double antenna, Single Conversion Super Heterodyne Diversity (I don't know whether it is true diversity or
phase diversity and the actual performance between these two),
sensitivity: =<6 micro volt @ 20dB S/N

Product 2: SHURE Camcorder VHF wireless microphone
Transmitter : model T1, RF Power,50mW;
Receiver: Non-diversity single antenna,
sensitivity: -109dBm (0.8 micro volt @ 12dB SINAD)

I will not consider buying the following product, because it cannot use bettery for the receiver unit. But do you have any comments for the comparison between product 1 & 3. Since there is only the difference between the Receiver Sensitivities and with the same transmitter unit VT3L; and I had the experience (very good performance, without any noise) in using an OLD model SAMSON VHF wireless microphone which is nearly the same as the product 3.

Product 3: SAMSON VHF wireless microphone
Transmitter : model VT3L, RF Power, 20mW;
Receiver: VR3TD Double antenna, Single Conversion Super
Heterodyne Microprocessor True Diversity
Sensitivity: <3 microvolt for 20dB SINAD, < 10 microvolt
for
50dB S/N

Thank you very much for your advise in advance!

Regards
Joshua Lo

If you have a K-Mart store in your area, try them.. I bought mine there for $2 each.. If I remember correctly, each slinky is equal to 65' of straight wire..

My dad always told me, "You get what you pay for." I guess since Tripod is free, you can't complain. I keep several pages on Tripod...never had a bit of trouble. I also keep every file on Tripod's site on my computer just in case there is ever a problem. Haven't had to use the backup plan yet and I've been with Tripod for about 3 years now. I guess it's a "sign" you should keep backup files of everything on your computer anyway. You HAVE been doing that haven't you? Ever "lost" anything on your computer at home?

If you are using the 2N3053 as a driver transistor... you should be able to put the pot between it's base and ground and use that to vary the output level.

You can probably find some "simple audio amp" circuits on the web as an example.

I picked up an unused SK-640 yesterday. This is the Eimac "Air-Flow"
socket which has NO integral screen by-pass capacitor. Does
anyone have any proven effective methods to adding an external
by-pass allowing the socket to be used in a VHF and/or UHF
4CX250/350/400 valved amplifier?

Look for circuits for 6 meter ham band recievers and then lower the
operating frequency by adding capacitance to the tuned cirucits.

Of course. I haven't any problem to build and use a few of them for each of
the amateur bands, although I wish will be wide enough to look at a couple
of them at a time. The HP one I had used with an scalar analyzer was 'only'
10MHz-26.5GHz if remember well.

I would be interested in the responses from r.r.a.h, however the people who use these things everyday (and have first-hand user experience and opinions) are probably to be found on news:rec.arts.movies.production.sound

I'm not sure switching from UHF to VHF is a reasonable reaction to your problems with a specific UHF microphone. My Sony UHFs have never given me any problems.

Todd, I think you're facing an uphill battle, for a number of reasons.

First, the folks who do the most building/experimenting are likely using CW. While I personally love CW, it really isn't the best medium for casual conversation.

Secondly, I think most of the hard core builders operate very little. Many seem to get on the air only long enough to test their latest creation, then it's on to the next thing. These folks are especially unlikely to want to spend a building evening yakking.

Still, you might keep an eye on just how much traffic the Homebrewer's Sprint draws this weekend. Might be a clue as to the audience.

As far as band, there's no right answer. Builders seem to favor 40 (QRM) and 20 (fickle). But no matter which band you choose, you will leave out most, if not for propagation, then for rigs/antennas.

1798. Help with 3-500Z amp problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-22 05:45:26 UTC
From: hawaiiansunset@hawaii.rr.com
Message-ID: <3abae118.7831687@news-server.hawaii.rr.com>
Source record: 53995

I just fired up an amplifier I rebuilt with 2 3-500z tubes,
it seems to have a problem - one of the tubes glows slightly red in
the standby position and pulls about 120ma at the same time. When I
transmit I can read on my Bird about 1kw key down.
The other tube in the key down position seems to get somewhat redder
than the other one (the one that gets red and is obviously drawing
plate current). Swapping the tubes from one position to the other does
the same thing. The tube in the rear socket seems to be the one
drawing the 120ma plate current in standby.
I have checked some things but have come up empty.
Can anyone suggest any ideas as to what may be wrong??

Is this grounded-grid? If so, I'd be suspect of the filament
choke. Another thing that comes to mind is some im-balance(sp) of
the filament voltage or its return, ie bypassing. Another thought
that comes to mind may be some remote sort of parasitic
oscillation affecting one tube by virtue of the wiring
differences.
I'm sure we'd appreciate to know about your findings.

Yes it is grounded grid - I did find the problem -
I had put some added circuitry in it - per Richard Measures
I found a defective resistor the resistor is a 30 Ohm 1/2 watt in
parallel with a 1800pf cap.
This resistor is on both sockets what it does is act as a fuse
protecting the grid from excessive current. And also help to equalize
the signal condition currents in two unmatched 3-500Z's.
The R/C parallel network puts the grid at rf ground.
I missed it because the resistor had cracked and I didnt see it.
What I failed to do was measure that one with my meter.
Some days you win some days you lose.

learning
> purposes, it's a great little part.

WB8RCR is right: with the 602/612 you kan make a single conversion receiver, add some coils (filter) - diodes - resistors - capacitors (detector) and you have a AM receiver that is a copy of the block schematic diagram. This was a practical test in the lab back in school...

Just download the datasheets from one of the manufacturer's websites, there you find all info you'll need.

PS: don't compare the specs of this with hi-end receivers hi...

Conventional resistors are next to worthless in fuse applications, especially this one. That's why we have circuit breaker panels and fuse panels not resistor boxes in our houses and cars.

Even fuses, which are designed to fuse circuits, require more time time to blow than the grid takes to fail. They mainly prevent fires. The saving grace is the 3-500Z has a very tough grid that rarely catches fire.

If you want to protect for excessive grid current, you need an electronic overload.

The resistor (and the rest of that black-magic) is just "hand-waving". For example, grid current runs about 100 mA per tube. That's 3 volts drop on peaks (time averaged by the capacitor over the RF cycle) out of maybe 60 volts or more of peak grid-to-filament RF voltage swing while the tube is in conduction. That will hardly offset any tube emission variations.

Hi,
at the moment I'm using a 0.01-1300mhz (Icom PCR1000) scanner hooked up
to the IF output of my Icom R-8500, but it feels like a waste of a decent scanner
to ONLY use it set to 10.7mhz FM 50khz filter.
I only use it for decoding data such as wefax, so I'd like to substitute the pcr1000
with a simple fm radio for 10.7mhz and 35-50khz bandwith.
Anyone got any schematics for a simple radio suited for this purpose or got any
other suggestions?

//Greg.

Aren't most broadcast FM receivers simply 10.7 mcs. receivers
with a tunable 88-108 mcs. converter at the front end?

Just thinkin' outside the box here....

Followup set to r.r.a.homebrew

You will need the help of a few others to get things started. You
will have to use bands that provide reliable propagation. I
would suggest 40M during daylight hours, 80M in the late
afternoon or evening or 160M late at night.

For UK and west European amateurs, there is a good homebrew
net on 3.727MHz SSB. Most but not all of the regulars are
running homebrew rigs.

Some people will say that you probably won't find enough
homebrewers to keep a net going. I'm a bit more optimistic,
there seems to be resurgence of interest in homebrewing
recently.

If you can't find any homebrewers in N9 land, turn your
beam towards EI. I'm on 28.985MHz SSB, most Sundays
at 15:00, 16:00 or 17:00 UTC.

Good Luck.

So why not take an old and/or cheap FM radio, whack off the front end, and replace it with a 10.7 MHz crystal or ceramic resonator. You might have to screw up the Q a little to get it that wide, but it shouldn't be too tough. Just what sort of shape factor are you looking for? If you don't need the skirts to be too steep, shouldn't be so hard to come up with an LC filter to get it down to 35-50 KHz.

Of course, I'm thinking WEFAX signals shouldn't be quite that wide, so maybe you could go narrower. It certainly is simple enough to do.

Theosus,

Inductance measurements are difficult to do. You can purchase an L/C meter from AADE which will do it over a limited range. Perhaps the best way to do it is to connect the inductance in parallel with a known capacitor and "grid dip" the whole mess. The inductance can be calculated this way. The technique is only an approximation because it depends on the precision of your capacitor! But it will give you close information. Accurate inductance values are not often needed anyway. that is why trimmer capacitors were invented!

There is more to crystal frequency than just the number printed on the crystal can. First, are both radios using the same "fundamental" frequencies? If they are not, changing one will leave you dangerously off frequency and may damage the radio. Second,. will the 161 ,Hz radio require realignment to work properly at 144 mHz? That is a long way to shift frequency! I would recommend you take the radio you want to recrystal to a real repair shop and have it done there!

Source record: 53869

Josh,

Mixers ar the most important part of a radio. Properly designed they can eliminate spurious signals. Badly designed they will let the spurious signals abound!

The NE602 is an easy mixer to work with. It is unfortunately no longer in production so finding some may be difficult. It has been replaced by the SA602, made by Signetics. These may also be difficult to find in through hole mount types. Also look at Radio Shack for any of the above and or the SA612 mixer. You may luck out.

Then read up on mixers and the mixing process in the Radio Amateur's Handbook. Don't have one? They are almost the bible of easy to understand radio explanations.

Mixers take two frequencies and add and subtract them. The reason you cant see them on a scope is you have no input frequency selectivity. If both frequencies are within the scope's frequency range you will see a mish-mash of both traces! Use a receiver that covers both frequencies. Say you mixed 4 mHz and 6 mHz. You would have a sum product at 1- mHz and a difference product at 2 mHz, along with the original 4 and 6 mHz signals! YOu may also have higher frequency products as well.

A trip through the ARRL Handbook and a pad of paper will start you on your way!

For Trade - or sell
Heathkit ultramatic keyer model SA 5010, including Heath "wall wart" power supply - both handles and all in apparently good shape - very little use...with manual. (I bought it over 10 years ago and it's been sitting in a drawer ever since.) Tag on bottom says it was serviced by Heath 3-30-82 in Benton Harbor Mich.

Want some QRP stuff in trade - to include maybe a transceiver in any condition, from kit to unfinished kit to fully built (prefer SSB xcvr but CW also OK) or what have you.
Parts I have plenty of so don't need them.

Will Sell - Offers? Please reply direct.

The simplest solution would be to extract the IF strip from an existing narrow-band FM receiver. Scanners, some cordless phones, 49MHz superhet walkie talkies, two-way radio receivers, and cellphones, will have FM IF strips intended for narrow band use. Consumer items are likely to have a 10.7MHz IF (though some of the cordless phones that I've looked at go from 49MHz directly to 455KHz), cell phones may skip 10.7MHz, and I've seen plenty of oddball IFs in two-way radio receivers.

But in any of these, you'll get the circuitry or even a module that takes in 10.7MHz at one end and gives you audio at the other. You get the IC and some filters, and since many convert to 455Khz, you'll also get the crystal to do the conversion. Many of the devices do the whole thing in one IC, like the Motorola MC3359.

They are probably better choices than converting the IF strip from an FM broadcast receiver. You'll get squelch, and a discriminator intended for narrow deviation.

Of course, it doesn't solve your filter problem in this particular case. The consumer items I've looked at use a 3-pin ceramic filter at 10.7MHz, though I haven't tracked down the bandwidth. I assume it isn't narrow, intended more for image rejection, but one could hope that it might be narrower than those used in broadcast receivers.

You could try to dig up a wideband 10.7MHz filter; there was a time when 30KHz was common deviation. Or maybe someone still manufacturers one that isn't too costly. I suppose then you'd bypass the 455KHz filter, put an IF transformer to get rid of unwanted output from the mixer stage.

You could stay with the existing 10.7MHz filter, but then dig up a wider 455KHz filter. Hopefully something nice and small, but

again one could dig in an old two-way radio for it's filter.

Or just get by with an IF transformer instead of the 455Khz filter,
or if you need something better, go with few coupled transformers.

There was an article in 73 magazine some years back about widening
a scanner for satellite reception. I forget the exact details,
but he basically did something like bypass the 455Khz ceramic
filter.

ON a whole different path, in North America television audio
is an FM subcarrier, and the frequency is 4.5MHz. I forget the
amount of deviation, but it is less than used in FM broadcast.
If the bandwidth isn't too much more than needed, it might
work out okay. Put a mixer ahead of it to convert from 10.7MHz,
and pop the sound module out of a tv set. I've even seen some
tv sound modules with 4.5Mhz ceramic filters.

Greetings...

I took a pair of Eimac 3-500Z's in partial trade for a rig I had.
Previous owner reports full power output from tubes with very low hours. I
have no way to adequately check them. Visually, they look good, with no sign
of internal gassing. In fact, they look beautiful! If interested I can take a
couple of digital pics and send them to you. Looking for best offer for the
pair above $250, and shipping will be via USPS Priority Mail. They will be
packaged VERY carefully and insured and guaranteed against breakage.
Unfortunately, that is the only guarantee I can offer. Payment via PayPal.com,
as I have obligations I have to pay via Paypal for purchases I have made and
need the money there. Make me an adequate offer and I'll get 'em in tomorrow's
mail! They are currently of no use to me, and I could use the money elsewhere.
Will take offers thru Midnight 03/23/01 CST. Highest offer gets 'em pending
payment via PayPal.com! I have a nearly impeccable track record here on the
NewsGroups, as well as the Ham classified sites and eBay under screen names:
N9LXX, blainefox, and fox7498!

73, es gud luck~~~

When I worked for one of the large telecoms we had some equipment
with some little devices called fusistors. Transistors that operated
as fuses to protect sensitive equipment. I guess you'll never see
these in a fuse box in your house.

I just bought the last 602's off a dealer in the UK, and he is now selling 612's - he didn't say that the 612's were coming to an end, should they should be OK to get.

I was intending to build a 40m CW transmitter driven from the VFO of my old Yaesu FRDX400 (tunes 5.4 - 4.9MHz) thinking that the 602 was just the job. I'm planning on 10W out maximum. Is the 602 a good choice?

I'm looking for a low distortion, low noise active mixer with DC compatible
output (lo from 1kHz to 15MHz)
So far I use AD831 devices but they are old and bulky.
Are there new ones that are as good or better in a smaller form factor ?

Thanks

Marc

>AH6JR

Fusistors are fused resistors, not transistors. Transistors are
semiconductors, and when they fail they normally fail shorted.
We want a conductor in a fuse, so it fails open, not a semi-conductor.

Fusistors are slow operating-time fuses. They are for extended
overloads for long periods of times, and ignore transients. They also
drop voltage (since they have noticable resistance). That's why we
don't see them in common applications where fuses are required.

Using a resistor as a fuse to protect a control grid is a waste of
time. Conventional fast-blow fuses are too slow to protect grids,
resistors would be a terrible choice.

Also, you NEVER want the grid of a tube to float. There are two major
problems caused by that.

First, assume the tube has a gas-related arc (very common in power
grid tubes used in PA's). The arc is normally from the anode to the
grid. If the grid is allowed to rise to the anode supply rail, the
transient simply dumps to the cathode. Anything connected to the
cathode circuit, including your expensive radio, can be damaged.

If the grid is firmly clamped to ground, it severes as a barrier to
prevent dumping full anode voltage to the cathode during a fault.

Second, if the resistor opens the tube may have enough leakage from
the anode to the grid to forward bias the tube. This is common in
large power grid triode tubes operated at high voltage.

You can not look at a tube, and tell it has no internal gas. You can
not tell if the tube is good.

I would think a responsable person would check the tube, before
selling it for money with and offering no warranty. Unless it was sold
for next to nothing.

Well believe it or not thats what we were told they were.
In fact the packaging was that of a to-5 device.
3 leads only use a certain 2.

The resistor acts as a fuse to protect the grid from excessive
current. This resistor has a cap in parallel with it. The bypass C
protects the resistor from RF-voltage. The grid is RF grounded through
this network.

1843. radiators for loops

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-23 17:00:45 UTC
From: aduffy@sprint.ca
Message-ID: <3ABB813D.2FBAB5A7@sprint.ca>
Source record: 53889

Does anyone have an idea of the effect of using copper strips instead of

the commonly used copper pipe to construct a loop antenna for 80m? ie
the effect on bandwidth etc. The 2 strips I have are 4.5" wide (there
is also safety edges on them) and 8' long for the main loop. This would
basically be just under the equivalent to a 1.5" dia pipe slit and
flattened. But you would have 2 radiating surfaces exposed as opposed to

1.

The reason I'm asking so I can modify a nice design I've come across to
compensate for the difference if any (smaller circumference etc).

Also would it be better to induction feed the loop using the same flat
material (if I'm correct in my assumption on how it works). Or to direct

connect as I've seen in other plans (with some form of matching setup).

Also I was wondering if it was necessary to mount the "tuning capacitor"

inside the loop or can it be mounted outside without changing any
properties of the loop (I don't know if there is any interaction of the
capacitor and the antenna or not)

And finally any ideas on controlling the cordless screwdriver to reduce
it's rpm without using gear reduction (if possible). I already have an
idea to limit rotation to a half rev but don't want the thing to rotate
in half a sec or less! :-)

Thanks in advance!

Tony

Just a voltage range isn't going to tell you anything. Take a look at
"http://www.digikey.com". On page 279 of their catalog they have a
listing
of varactor diodes.

Lots of other catalog vendors carry varactor diodes. Just go to
http://www.yahoo.com and do a search on "variable capacitance diodes".
You will get a bunch of links to data, like this:

http://members.tripod.com/Malzev/comp/diode.htm

http://www.chipdocs.com/catalog/tree.html?ReR=E4&selid=42

http://zeus.cedcc.psu.edu/semi/vvcindex.html

Except for a few special devices, most of them are for small capacitance
ranges.

I understand that's what the claim is. I'm not trying to argue, it's just that resistors make poor fuses in any application that is time-critical.

>You have excellent points here Tom, but as I said maybe you need
>to talk to Richard Measures.

It only helps to talk to someone who is interested in how things actually work, like you. Electronic protection devices are much faster and more reliable than fuses, and they are especially better than resistors.

I assume you did install an energy absorbing resistor in the high voltage lead, between the filter capacitors and the RF choke? That's what really helps, of you have a HV fault in the tubes.

I use my Jet drill/milling machine (which I got at a surplus tag sale for
$250)

But before that, I used metal nibbler tools, or a series of drilled holes
smoothed with a bastard metal file.

I've used a "brute force" method by marking the rectangle ans then using a dremel drill with a grinding wheel on the end of it to grind through the metal and then out to the shape I wanted.

I had to be careful to not snap the grinding disk, but it was a relatively painless way to get the cutout.

> listing
> of varactor diodes.

Digikey is a great place for stuff, but they are pretty weak on RF stuff. I think a peek at the catalog will show that what varactors they do have tend to be surface mount.

Dan's (http://www.fix.net/dans.html/) does usually have the varactors that are useful for HF, mostly in TO-92. You will find the MV2115, MVAM109 (which I see Dan's doesn't have right now), MV209 are pretty popular. Sadly, Dan's only takes snail mail orders which means you wait a long time for the mule train to make the round trip.

Quite often a few part numbers are available from Radio Shack online (http://www.radioshack.com). For small dollar value orders, rs is often a good bet beause their shipping is attractive and their prices tend to be not too bad, either. However, they have the worst web site on the planet, so finding things can be a real chore. When you order from rs always check the 10 and 100 quantity prices. Sometimes there can be some very pleasant surprises. A while back I got some MV2115's there for around 50 cents if I recall, by ordering 10 instead of the 3 or whatever I had intended.

RF Parts (http://www.rfparts.com) also generally has varactors. I've never ordered from them so I can't speak to their service. They seem to be a little pricey.

Hope this helps

A couple of comments on the 602/612.

The following is my third hand understanding of what is going on here. It's largely based on second hand comments, rumor, and innuendo, so it may not be accurate. But it does fit...

The NE602 production was bought by Phillips some years back. Phillips uses the SA numbers instead of NE. The NE602 is no longer available, but the SA602 is, and it's the same part.

The SA612 is essentially the same part as the SA602, except that the SA602 gets some tests which the SA612 does not. The 612 has the same specs, but they are by design rather than by test. The price reflects this ... 2.25 vs. 2.95 at radioshack.com.

The big fire in the southwest (Arizona was it?) last year knocked out the Phillips plant that made these things, and they were already in short supply. Since the part is mostly used in cell phones, the surface mount versions were produced first and in larger quantity when the plant went back in service, so SM versions are now widely available. The DIP version was virtually impossible to find a few months ago, but now it's becoming available sporadically, but more and more often as supply catches up.

The 602/612 is a dandy mixer, and the only real choice if your objective is low power. The part suffers badly from intermod, so if receiver performance is a more important design point than power consumption, passive mixers are a better choice. A well-designed 602 receiver can be a heck of a rig, tho, so don't discard it as a second-rate part. Just be sure to take care with LO levels and front end filtering.

With respect to Chas' VFO problem ... if you have a few volts out of your VFO, a ring diode mixer might be a better choice. You can make one up with 4 1N4148's and a couple of FT37-43's. For a receiver, schottky diodes might be a better choice. The problem is that in a receiver you need to add some amplification before you go into the mixer, which adds complexity, cost, and power consumption. Nothing wrong with a 602 in a transmitter, and there the IM generally isn't a problem. But depending on your junk box, building from scratch might be better, since you probably already have enough level, and power consumption is a little less of an issue anyway. MiniCircuits has some really high performance mixers like the TFM-2, but they are pricey. The gold-plated receiver solution, however, is likely to have a MiniCircuits mixer in it. Just don't expect to run it off batteries!

>
I've seen low-wattage carbon film resistors used as "fuses" in repeater controllers (phone line) and in computer modems. They seem to do the job--failing open on a high transient. I've also seen the results of having someone replace the resistors with a piece of wire on a CAT1000 controller because they got sick of having to replace resistors two or three times during lightning seasons. They weren't so lucky the next time.

Could it be the time constants (low thermal mass) for low-value and low wattage film resistors make them suitable for some applications where transients are a problem? There were other devices beyond the resistors that limited the peak voltages in the two devices I mentioned.

You might also consider tuning with a varicap diode. Such a diode changes capacitance with a change of
reverse voltage across the diode. Such a radio could be tuned remotely
with a multi turn pot.

Hi,

(I do seem to have plain text rather than HTML on ...)

I've used the National LMX2301 and LMX2306 parts. With the 2301 you only get to 160 MHz, but you do not have a prescaler. Sometimes the fixed divide in the prescale will keep you from getting the highest comparison frequency.

Both parts are fairly cheap and easy to set up with a simple PIC loader.

NEW PROGRAM TOPHAT1.exe

TOP CAPACITANCE LOADING OF SHORT VERTICAL ANTENNAS

Loaded by any number, zero upwards, of uniformly-spaced radial rods or wires, of specified length and diameter, circled by a ring of wire. With only one radial you have an iverted-L. By entering a large number of wires the hat will have the same capacitance as a disk of close-mesh chicken wire.

Enter antenna height and diameter, frequency. Guidance provided on estimating ground loss resistance. A coil is always needed either at the antenna base or incorporated in an L-match. Coil Q is asked for.

The performance of a short top-loaded antenna is generally several dB better than a coil-loaded antenna of the same height with the coil fitted 2/3rds of the way up the antenna. With a largish top hat the antenna current is sufficiently uniform vs height for there to be little or no advantage gained by inserting a coil in the antenna. It can then be incorporated in the L-match or an automatic ATU and the antenna can be operated multi-band. With coil loading multiband working is not possible except with screwdriver-type antennas.

The superiority of capacitance loading is due to the smaller inductance needed to maintain resonance. If the coil has the same overall dimensions, and hence approximately the same Q, the coil loss resistance will be reduced for no increase in loss in the hat.

Sweep the principal input parameters over wide ranges using adjacent up/down keys on the keyboard while observing corresponding changes in radiating efficiency. The improvement in dB is calculated due to the hat compared with no hat.

Download TOPHAT1, 44 kilobytes, in a few seconds from website below.

30 kHz deviation was dropped somewhere around the mid 60's. I was seeing new radios wit 15 kHz while I was in high school, and I graduated in 1970. Also, most of the wideband stuff I've seen used a lower IF frequency.

TV uses the same deviation as FM radio. I've worked on the transmitters at three tv stations, and took care of the equipment in a CATV headend. all used the same modulation.

You could add a couple more stages of 10.7, and the extra transformers will narrow the signal a little. I've build outboard amps and a few got so narrow I had to add a resistor across the transformer windings to lower t Q to regain some bandwidth, at the cost of some gain, but I had an extra 10 dB to burn, so it worked out well. You might get by with a tuned trap on each side of the passband to reduce the bandwidth, but watch out for excessive phase shift.

The biggest problem with excessive bandwidth is lower recovered signal level, if there is no interfering signal in the passband, a couple Db of gain will take care of the problem.

One way to run a dc motor at low speed without loss of torque is to use a low duty cycle drive signal, at full voltage. It shouldn't be of so high a frequency that the motor just averages it, or so low that the pulsations are troublesome, so that you get pretty smooth motion with full torque. Maybe 5 or 10 pulses per second, and then the motor will be variable from very low speed to full speed as the duty cycle goes from a minimum value to 100%. A simple way to reduce the speed would be to operate the thing on half-wave rectified ac of appropriate voltage, which would give you a 50% duty cycle with no more trouble than the diode. If that was slow enough, you wouldn't need to do anything else.

I'm not familiar with transmitting tubes, but I remember that receiving tubes used to have a silvery getter that would turn white if vacuum were lost. Don't these transmitting tubes have something similar, or can they be just somewhat gassy without losing vacuum?

Looks like you are not from around here..hihi. I do not know the TV and FM band standards in the VE land but in the US there is a big differance in the TV and FM deviation. I think ther TV uses 25 khz for the audio and the vidio is AM . The FM stations use 200 khz for the deviation. Bad thing about the standards are there are several differant ones depending on where you are at.

If by "between" you mean "in series with", then it is unlikely to be a capacitor(!) More likely a fuse or fuse-like protective device.

I was very pleased with the service from http://www.primecell.com/ Excellent work, fast and inexpensive. Couldn't ask for a better combination! I have no connection with them except as a satisfied, paying customer.

Actually at least in the U.S., it doesn't. The peak deviation for TV audio
is 25KHz; for FM radio it's 75KHz. Pretty much a moot point as both figures
are much greater than would fit in a 30KHz-bandwidth filter.

(the quoted "200KHz" deviation for FM is actually the width of the assigned
channel)

No. Transmitting tubes have the gettering agent coated on the anode
(in 3-500Z's).

But considering a receiving tube, even if the gettering material that
deposits on the envelope (the "silver coating you see) is NOT white,
it still doesn't mean the tube is good.

It wouldn't be advisable to purchase any tube without a warranty ,
especially a 3-500Z. The exception would be if you got the tube for
next to nothing.

Virtually all of the common failures are not visible when looking at
tubes. Because the tube "looks new" doesn't mean it is good. A
significant percentage of brand-new 3-500Z's are defective, or fail in
a short period from manufacturing defects.

An entire batch of 100 3-500Z's I received from Eimac right before
they closed glass tube manufacturing were defective!!!! Probably
because the employees knew they were getting laid off.

Clinton,

It's a thermal protector. They are mandatory, not for charging, but for safety as a protection device in case the battery gets shorted. When you short out a nicad/nimh battery, they unload all the current they can through the short. If the shorting conductor is solid metal such as a coin, the heat generated within the battery can instantly reach temperatures high enough to cause spontaneous combustion of anything around it that will burn. That's why they tell you never to short the things out. The thermal cutout is sandwiched between the cells to easily sense the heat and open if it gets above a rated temperature. You can get away with not replacing it, but don't ever let that battery get shorted!

Hope this helps,
Rick

That is quite strange, since as far as I know, the 75 kHz deviation is used for FM radio all over the world. With stereo, the baseband bandwidth is 30 Hz to 53 kHz, which in addition to the deviation determines the required IF bandwidth. However, the audio deviation for TV sound is 50 kHz in Europe and apparently 25 kHz in the USA. The mono baseband bandwidth is only 15 kHz, thus the emission is much narrower than in FM broadcast radio.

Looking at various 2 or 3 pin 10.7 MHz ceramic filters from Toko and Murata, their -3dB bandwidth starts from 110 kHz, the 180 kHz filter is intended for mono, while the 230 .. 280 kHz filters are intended for stereo. The Murata 5.5 MHz subcarrier filter (Western Europe) has a 150 kHz bandwidth, while the 6.0 MHz subcarrier filter has 160 kHz bandwidth (UK). I guess that the corresponding filters for the US 4.5 MHz subcarrier frequency would be even narrower.

The stereo sound system for TV in the USA is similar to that used for FM.
(we don't have NICAM) It provides one subcarrier at 31.5KHz (twice
horizontal sweep) for L-R and a second at (I forget, I think it's around
78KHz) for a second audio program, intended for second-language translation.

While I'm not sure what bandwidth *is* used for stereo TV IF filters, I
suspect it's actually *wider* than that used for FM stereo, because of that
subcarrier intended for public use.

(incidentially, I have 110KHz Toko filters in the narrow position of my FM
tuner. It does wonders for DXing.)

Paul is absolutely correct about the TV and FM deviation standards.
FM radio - 75kHz universal.
TV PAL - 50kHz.
TV NTSC - 25kHz.
Ian.

1888. WTB: Power Transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-25 21:54:21 UTC
From: Michael Wachur <KA1YY@EROLS.COM>
Message-ID: <99lpdu$16u$1@bob.news.rcn.net>
Source record: 53933

Hi,

Looking for an older power transformer with the following specs:

Primary: 120V

Secondary:
275v-0-275v @ 90ma (B+)
6.3v (filament)
5.0v (filament)

The HV secondary winding is approximate and I can use something from
250v-0-250v to 350-0-350. One from an old 50's TV chassis would be great.
Let me know what you have, condition, and price.

Thanks,
Michael

Source record: 53934

I'm looking for a nice PLL chip.. But it seems like nobody, Motorola, or National makes any in DIP form anymore.

Everything is SOIC or stranger.. Is there any easy way to use SOICs on a PCB or are their DIPs somewhere?

1890. FS / FT: Famous HRO Dial w/variable caps

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-25 23:23:44 UTC
From: k5bdz@aol.com
Message-ID: <20010325182344.20307.00001381@ng-mq1.aol.com>
Source record: 53935

For Sale for $110 shipped ground to U.S. or trade for QRP SSB xcvr kit:

A National HRO dial, including gear reduction system and two variable capacitors (right angle drive for each).
The HRO dial comes complete with black knob about 2 1/2 in dia, with a skirt that has 5 slots through whick is visable numbers that change as you turn the know CW or CCW revealing 0, 10, 100, 250, 450, etc through 500 at the end of its range. (Newer hams may remember the similar Kenwood TS-820 dial read-out).
The skirt appears to have been gray colored (or possibly even bronze) at one time. The dial is attached to the gearing mechanisum behind, with two (yup, two) appearantly identical variables right angle driven out left and right. Both caps mesh / unmesh together. Would guess capacitance approx 300 pF each.
ALSO I have the matching metal arc'ed spacer for its brother arc'ed marker that goes on the panel behind the dial skirt for read-out, with arc numbering 0, .1, .2, etc up to 1.
The main dial skirt appears someone tried to clean it. Appears minor surface scratching but no gouges or deep scratches seen. Should buff out very smooth in all likelihood.

I'll ship it properly wrapped and cushioned.

In answer to the question, S9 is generally taken to be 50 uV in 50 ohms, and each S unit represents an increase/decrease of 6 dB. The problem is that no two receivers are the same!

Dr Ulrich Rohde in "Key components of Modern Receiver Design - Part 1 (QST May 1994) suggests " - that we redesign our signal meters along the lines of those used by our professional collegues, calibrating them from -20dBuV (0.1 uV in 50 ohms) to +100dBuV (100mV in 50 ohms) - ". This implies that the receiver has a very wide range AGC that is well characterised to give meaningful meter readings. Perhaps this is why non-professional equipment doesn't do this.

So it appears as if your TV stereo signal is quite similar to the FM broadcast signal. Since both systems must be compatible with old receivers, the stereo deviation must be about the same as the mono deviation and thus, the demodulated mono signal is slightly weaker and the mono audio SNR is 1 .. 2 dB worse when the stereo is switched on.

Thus your TV audio deviation must still be about 25 kHz and the FM broadcast deviation 75 kHz. You might have a second language subcarrier on a high subcarrier frequency, but isn't the SCA transmission still in use on some FM broadcasts? With similar baseband bandwidths, but quite different deviation, I do not see, how these both signals could have similar bandwidth.

It should be noted, that the Carson's rule should not be applied with such a low modulation index and complex baseband signal. Looking at the Bessel functions for a modulation index of 0.3 (US TV audio), the second set of sidebands are very weak compared to the situation for the modulation index around 1.0 (FM broadcast). Thus, I would guess that quite satisfactory TV audio reception (with second language present) should be possible with 160 .. 180 kHz IF bandwidth (only first order sidebands), while broadcast FM might require 300 kHz with SCA present, assuming two sets of sidebands (although 220 kHz might be sufficient, if the SCA deviation is so low that the second pair of sidebands are weak enough).

The problem is highlighted in your response, where you say "generally
taken". S-9 has no formal definition, except "extremely strong
signal". As far as S-meters go, it is whatever someone makes it.

As a matter of fact, the ARRL Handbook gives different suggestions for
S-9 on different frequency ranges.

Each S unit does NOT represent a change of 6 dB. As a matter of fact,
most receivers try to use 5 dB or less per S unit. 6dB per S unit is a
suggestion that never was widely accepted.

>Dr Ulrich Rohde in "Key components of Modern Receiver Design - Part 1 (QST

The signal bandwidths are different (with FM having more) but FM subcarriers
(of course except for the 38KHz L-R) are not meant for reception by the
general public. So it's acceptable for a typical FM receiver to use a
narrow filter that doesn't pass the SCA. The special FM receivers that
are intended to receive the 67 and 92KHz subcarriers *do* require a wider
filter.

Thanks John!

I would have never though of doing something like that. Any ideas where I could locate a circuit diagram for this supply?

Using a couple of batteries and a ammeter I discovered without a load on the output shaft, the screwdriver draws about 800mA. I am able to reduce the rpm with lower voltage, but it looses most of it's torque and the little 3V power supply I picked up at the surplus store warms up after about 10 min (it's only rated at 240mA, although during use it wouldn't have much of a duty cycle). Now under load of the capacitor it may prove to be useless all together.

It seems the best would be to use a mono connector. If you are recording a stereo source and use a stereo cable you are likely to only get half of what you are trying to record.

Tony,
Unfortunately, I don't have a circuit at hand. You could try the half-wave rectified ac at full voltage first, to see what speed reduction you would get. Beyond that, you would need a duty cycle controller and an amplifier or driver. For the amplifier, I think there are a lot of vmos fets that could handle more than an amp, and that could be driven very easily from logic. Maybe you could use a cmos 555 timer with a variable resistor to produce the variable duty cycle. It's been years since I've done any of this kind of thing, so it wouldn't surprise me if you could get a chip to do it all in one package, but I'm at a loss for a reference. Maybe somebody else in the group has an idea?

1903. Where can I find Motorola pager schematics to use for design?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-26 21:48:36 UTC
From: Josh DeWinter <dewinter@wsunix.wsu.edu>
Message-ID: <99od3m$6ej4$1@murrow.murrow.it.wsu.edu>
Source record: 53798

Hi.
I am looking at an old pager I bought recently, a Motorola BPR 2000. Its an older 80's - early 90's audio pager. It really fascinates me that this thing runs so well off of only a single AA battery, but yet there are models of this same unit that can operate anywhere from 30 to 900 MHz. I would like to see how the heck they do it, so as to model a circuit of my own from this design. If anyone knows where I could get a schematic for this or any of the Motorola pagers, I'd be grateful.
I'm thinking this may still be proprietary, and hence secret, but occasionally I will find older user manuals that included schematics. (Who knows why they did, but they did). Radio Shack was famous for this with alot of their RF equipment.

Thanks for your help.

Hi,

Have you been soldering for years and now are getting cold solder joints? Are you aware that flux has a limited lifetime? Did you buy that 1 Lb of solder at a flea marked for next to nothing and find that it doesn't solder well?

Flux has a limited life. This includes the rosin flux in the core of your solder. You can still utilize that solder with an external application of flux. Kester sells a "tin" of flux, SP 44. This is a paste and seems to be mildly active. I have also tried flux from several other manufactures and have found out that a very active rosin flux is needed when repairing old solder joints with old solder.

The most active flux that I have found is sold by Radio Shack. It is a paste flux in a squeeze tube. Works great and will help you to produce those beautiful shiny joints again.

Does anyone know who makes this flux for Radio Sack and how it can be purchased direct? I would like to buy this flux in another container. It is difficult to squeeze this stuff out without making a mess.

Regards,

Bob

I am using some solder that is almost 20 years old. Still works
fine and makes good looking joints. I do use 63 / 37 solder
rather than the normal 60 / 40 type. I find that it has always
made better looking joints and does less damage to the circuit
boards.

Most paste flux is acid based and shouldn't be used for electronics.

I have been using flux core solder that is very old and it's just fine. I have some paste flux too but the only think I use that for is 'tinning' the iron tip and any kind of non-electronic work such as outdoor metal, etc. And when I do that, I use 50-50 tin-lead rather than 63-37 or 60-40. It's stronger although does require higher temperatures for a good joint. But I don't use a regular soldering iron - I use a propane torch with solder tip for such stuff.

FM channel spacing is 200 Khz, but the deviation is +/- 75khz. TV uses
25 khz for the mono channel, but the transmitters are made to handle a
second channel, and use double the horizontal deflection rate to
multiplex the two channels. That is 15,734 hz X 2, or 31,468 hz, and the
second channel is above it. Look at the Harris site, their transmitters
go well beyond +/- 100 khz deviation with low distortion and phase noise
in the recovered audio.

TV video is vestigial sideband, not AM. The full upper sideband is
transmitted, along with the carrier left, and a small part of the lower
sideband.

You might find some data on low power paging receiver chips on Motorola's semiconductor website. Did you know that the receiver in that BPR 2000 is off most of the time? It turns on long enough to look for a preamble code from the paging transmitter. If the preamble code is heard, it wakes up and listens for its own message. Otherwise it goes to sleep for a while. If you monitor the local oscillator circuit with your scanner, you will hear it cycle. I think Motorola got in a patent dispute over this years ago. I used to hear my neighbors beepers (when I lived in the city) local oscillators turning on and off. (pretty wierd!)

best I can offer is this little tip.

get a cheap DIP socket, and a fine soldering iron, and some wire wrap
wire.

simply "extend" the legs of the SMT to the sockets on the DIP then
adhere the SMT into the centre of the socket with some glue.

Yes. It is generally accomplished by straight AM modulation followed by a filter to roll off the lower sideband. (in older transmitters, a HUGE stack of piping was used to chop it right before the antenna. More recently, modulation and filtering are done at low level & a bunch of linear amplifiers used.)

Vestigal Sideband AM is used by all terrestrial BC TV transmitters for
their video / vision signal.
Still wonder why they dont do it for AM radio, and use the free coming
bandwith for extra audiospectrum.

I've seen some luck in similar situations using a dremel with either
the router attachment, or the router-like cutting guide. Both are
available at WalMart, Lowes, and Home Depot in this area. The drill
bit style cutting bit seems to give a pretty smooth edge.

1921. Suitable IC's for frequency synthesizer

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-27 18:26:38 UTC
From: troglodite@aol.com
Message-ID: <20010327132638.22126.00001937@ng-fc1.aol.com>
Source record: 53816

Greetings,

I am in the process of designing and putting together a CW transmitter similar to one I built in 1956. Though this is a vacuum-tube project, I am giving serious thought to incorporating a frequency synthesizer due to the cost of crystals these days. I'll be operating on 3.5, 7, and 14mhz, all convenient multiples. (sort of) Since I'll have to switch the driver and final coils, I could also reserve a deck of the bandswitch for programming the synthesizer output to the correct frequency range. The main frequency control would be a rotary encoder and digital display of exact frequency. I could probably pick some specific increment like 10Khz/step, or possibly make this settable.

Anyone have any idea of suitable IC's for this purpose, or perhaps even an available circuit board? Some of the Motorola chips look like they might work, but I'm not so sure how "clean" the built in oscillators would be. Anyone been down this road? Thanks in advance.

1922. Kenw. TS450 low output on 160M

Newsgroup: rec.radio.amateur.homebrew

From: mark <mfvernooij@wanadoo.nl>
Message-ID: <3ac0eca2$0$16183@reader5>
Source record: 53817

My Kenwood TS-450sat seems to have a problem on 160M. It's only gives 6 or 7 watts output on 160 meters. Power on all other bands is +/- 100watts. I bought this radio 2 years ago and never checked the power on 160M since i do not have any low band antennas. The radio was modified for receiving and transmitting full hf coverage at the time i bought it. I thinks there's something wrong with this modification. Some countries do have +/- 10 watt maximum power limit on 160M. Maybe the mod isn't done the right way (wrong rectifiers removed). I suspect the radio is in a special modus now, i know you can get a 50 watt on 28MHz limit if you cut the wrong rectifiers.

Is the problem really caused by a wrong modification or is it a defect in the radio?

tnx, Mark.

>bandwith for extra audiospectrum.

Because when they want to make a change that requires investment in
transmitting equipment and likely incompatability with many existing
receivers, it is better to make a leap forward instead of a small
incremental change.

Experiments are now done with digital radio on shortwave. That seems like
a better followup for AM than VSB.

Same holds for TV of course... the old VSB standard with added color
subcarrier is still used and was never replaced by all the new inventions
like D2-MAC and HDTV, even when these provided a superior picture.
And this has proven to be fortunate because now that they have waited
until digital technology has become practical, better solutions are
possible. Even with digital technology, experiments have shown that
some modulation schemes are better than others, and early adopters have
become victims of that.

Even in these days, where services that require dedicated equipment that
is useless without the service provider appear and disappear within 5
or 10 years, it seems worthwile to think a little more before changing
a standard like radio or TV broadcast.

About six months ago I needed to breadboard a circuit which used chips that were only available in soic. I found a company that mades tiny circuit boards with dip legs, in whatever leg configuration you want (6, 8, 14, 16, pins, etc). You simply take your soic chip, solder it to the top of the adapter, and presto...it's now a dip.
Go check Newark or Digikey. I bought it from one of them. Hope that helps.

I've used the "solder little wires to a dip header" approach. It works, but it's *extremely* tedious. I wouldn't advise doing it unless you absolutely have to. I presume you have good eyes and/or a decent magnifying glass.

About six months ago I needed to breadboard a circuit which used chips that were only available in soic. I found a company that mades tiny circuit boards with dip legs, in whatever leg configuration you want (6, 8, 14, 16, pins, etc). You simply take your soic chip, solder it to the top of the adapter, and presto...it's now a dip.
Go check Newark or Digikey. I bought it from one of them. Hope that helps.

Hi,

If you do the transmitter with tubes and crystals you have a piece of history. If you do it with tubes and a modern synthesizer you have a novel piece of gear. Depends on what you are really trying to do.

Compared to the price of the vacuum tubes in the transmitter I'd say that the price of the crystals has gone down since 1964 (you have a couple of years on me ....).

The traditional surplus houses have pretty much gone into other lines so that source of crystals is not what it once was. If you hunt around though I think you will find crystals pretty cheap out there.

If you hit the hamfests you can still find ft-243's at the same $2 to $4 that they have been more or less forever.

The last time I got into selling modern crystals they went for < $5 each and they sure didn't sell very fast. I have seen others trying to sell modern parts and not having much more luck than I did. I'd at least hit a local hamfest and make a couple of guys some offers.

Just a thought.....

I would think the reason that DIP's are no longer available, is that the newer packages have less inductance (and capacitance) and are more suitable for UHF applications.

When I read the original post, my thought was that he should build
a crystal transmitter, and then build an external synthesizer. This
was a fairly standard scheme in the old days, except the external
unit was a VFO (which usually worked ond fixed range, and was multiplied
to frequency in the transmitter).

Putting things in two boxes has some advantages. You can get
the transmitter working with a crystal or two, while you work
on the synthesizer (or work towards your General license!). You
get the synthesizer away from the heat in the transmitter. It might
be easier to shield the synthesizer in a separate box (keeping the RF
out of the synthesizer may be a concern otherwise), and a smaller
box may make for better mechanical stability.

Of course, all of this applied back when the VFOs were in external
boxes, too.

And having a crystal controlled transmitter means that someone
could easily build a VFO as well as a synthesizer, for the ultimate
in boasting.

These are sound and logical reasons, but it's not engineering
considerations that have seen the demise of DIL chips. It's the simple
economics of pick'n'place with holes.

They do, tune in CHU on 3.330 MHz first select upper and then lower sideband, one is missing and the signal still sounds good on an AM detector. Other shortwave broadcasters do the same.

Bob,

Thanks for your reply. The intent was to build is as a "classic" design, with a front panel socket for the traditional FT-243 crystal. The synthesizer would be external and plug into the back. Tube linup is 5763 oscillator, 2E26 driver, 4-65 final. Probably will use SS diodes for the power supply, though the original used 866A's, but I do recall they generated some hash on 80M.

Anyway, the intent is to get back into CW, and also to recreate the rig I built many years ago - in somewhat updated form. I'm already running an all vacuum-tube station using a Hallicrafters SX-117 and Heath HX-10 transmitter. I've also restored several other pieces of old tube gear, including a Hallicrafters SX-28, which is what gave me the itch to get back into the hobby, and the incentive to finally get my General. Now I just want to build something from scratch again.

tried some different RF power meter circuits using two instruments,
but the instrument for reflected power still has some minimum
deflection, seems impossible to null it down to zero. Is this normal?

One meter has a resistive RF-divider from one RF-connector, the other
uses capacitive divider - 1-20pF trimmer in series with 100pF - to
ground. The probe is built into the small Eddystone 7134 die-cast box

Is it just the problem I have to live with or is a better circuit
recommended?

The idea behind this is to insert a DC blocking capacitor at each
end of the transmission line. Then apply the DC AFTER the capacitor
on the input end and take it off BEFORE the capacitor on the output
end. A crude ascii diagram is below. You will need a fixed width
font, like courier, to view it properly.

```
|| COAX CENTER ||
VIDEO ------||------------------------------||------ VIDEO
|| | | ||
| |
DC PLUS ---------- ----------- DC PLUS

DC MINUS COAX SHIELD DC MINUS
AND VIDEO ------------------------------------------ AND VIDEO
GROUND GROUND
```

The capacitors keep the DC voltage from causing problems on
either end of the transmission line. This is a common thing
to do for say, controlling a remote antenna relay. To the RF,
a capacitor of 0.1 uF would look like a short and allow it
to pass to the output. The DC voltage sees the capacitors a
open circuits and blocks.

However, what you need to remember is that the capacitor value
also sets the low frequency limit. With RF there is not much
of a problem because it is usually well above the frequency
where roll-off starts. Baseband video, on the other hand, may
be a little bit of a problem. A composite base band video signal
contains some very low frequencies and might require some
fairly large capacitors to prevent them from being attenuated.

It's not very likely, but, your camera setup may use a DC bias
on the video that would be eliminated by such a setup. In that

case, this kind of setup couldn't be used at all.

But, it's simple enough to give it a try. I would start with capacitors around 10 uF and work my way up. If it seems to be loosing sync or seems unstable, increase the capacitor size.

->sideband.

Mr. Terrell, you are beginning to have less and less credibility with me. First the FM and TV audio deviations are equal, and now the video is not AM.

The video IS AM. It is single sideband full carrier AM, but it is still AM. Look at the designations for SSB and TV. They both start with the letter A, which is the AM designation (as opposed to F or P). Last I looked TV single sideband video was A5, or did I miss something?

To be perfectly honest, it's *not* single sideband. (but it is full carrier
AM) A significant part of the lower sideband is transmitted - the lower
frequency components including the synchronizing signals. Don't have
standard in front of me but I want to say the LSB is rolled off above
750KHz.

No, Mr. Terrell is correct. It is not single sideband. It is not full AM. It's vestigial sideband AM. All of the upper sideband, the carrier, and part (but, only part) of the lower sideband is transmitted. Thus, it would be technically incorrect to call it single sideband since parts of both sidebands are transmitted. It would be incorrect to call it AM unless you specifically specified that it was vestigial sideband AM, since the term AM by itself is usually understood to be double sideband with the full carrier.

Oops, I forgot about one thing. There needs to be chokes on
the power supply leads.

```
|| COAX CENTER ||
VIDEO ------||------------------------------||------ VIDEO
|| | | ||
| |
DC PLUS ---OOOOO-- --00000---- DC PLUS

DC MINUS COAX SHIELD DC MINUS
AND VIDEO ------------------------------------------ AND VIDEO
GROUND GROUND
```

Where --00000-- is a choke

The chokes keep the low impedance of the power supply from
shorting out the video on the coax. For a system with RF,
instead of baseband video, simple RF chokes are used. For
this one some pretty high valued chokes may be necessary.
Their value may be so big that there would be to big of
a voltage drop to be pratical.

Like I said before, doing this with base band video may be
a problem. Maybe someone else has a better idea.

Assuming you have a resistive load, it sounds like you either have a RF ground loop problem, layout problem, or poor/improper component in your meter.

RF layouts are very tricky at times.

Did you copy ot from an article somewhere?

There was an article in a 1963 QST about build9ing a tube-based synthesizer. As a matter of fact, I have the exact unit pictured in the story - purchased at a hamfest for $5. It's a crystal/mixing synthesizer that uses about 15 xtals to generate 5.0-5.5 in 10 kc steps, and a VXO for interpolation between the steps. It's pretty simple, uses 3 or4 tubes, and mostly CB xtals.

Hi Pete,

I already outlined the reasons why they are a bad idea in applications
like protecting control grids.

Lightning damage is a catastropic failure, not a fuse issue.

It would be foolish to use jumper wires for lightning surge limiting,
and equally foolish to use resistors or fuses for over-current
protection on grids.

In the case of lightning, film resistors might be OK in some
applications because the surge current is many thousands of times the
operating current. In a grid, it is an entirely different problem. The
overload that damages the grid can only be twice the normal current,
and in that case even a normal fast-blow fuse won't work. A resistor
would be nothing short of idiotic.

Doug!

I've just finished a direct conversion HF receiver project, which had at its heart a DDS (Direct Digital Synthesiser) for the LO. DDS's are GREAT! I'm resisting the urge to do the hard sell... :-)

Let me whet your appetite...

Analog Devices (www.analog.com) have a product line-up, the more affordable being:

Maximum Fout = 12.5MHz (Clock = 25MHz)

AD9832 <- Used in my design
AD9831

Maximum Fout = 25MHz (Clock = 50MHz)

AD9835
AD9830
AD7008

They have other devices that permit the generation of frequencies up to 150MHz, but the above are probably of more interest to you.
OK. So what do they do?

Simply load in a 'frequency control word' of 32 bits, and it will generate an output sinusoid (at ~ -3dBm into 50 ohms) according to:

Fout = Fclock * Frequency word / 2^32.

This way, you can change the output frequency in millihertz steps from DC - Fclock/2.... :-)
Unlike a PLL, there is no loop stability or lock time issues (the frequency is changed in a fixed period of time (~10 clock cycles)), and no VCO requirements, as the chip outputs an analog voltage that only needs some low pass filtering....

The noise floor is typically -70dBc, with all other spurs being kept below -40dBc (ample purity for most amateur applications).

In my design, I used a Microchip 16F84 PIC processor (~A$10) to scan a keyboard, and when a new frequency was keyed in, send the new frequency control word to the DDS. The PIC also simultaneously updated a 4 x 7 segment display to keep me informed as to the current output frequency. I can send a copy of the schematic to you if you would like, as I imagine it will be relatively straightforward to adapt it to your needs...

Go look at Analog Devices wesite!
(They also give out free samples too... it worked for me!)

Cheers,
James VK2XQF :-)

Yep. It's sure *close* to SSB but not quite the same thing.

I don't know why they use the VSB but I would venture several guesses:

- Too hard to completely strip the LSB without causing excessive phase
distortions in the lower parts of the USB

- Too hard to completely strip the LSB without the filter's cutoff frequency
drifting across the carrier & causing overmodulation

- Desirable to have extra energy at the lower frequencies which both contain
the synchronizing information and provide the most visible part of the
picture

Some of this keeping in mind that the VSB system was chosen in 1941,
abilities we think are commonplace today weren't 60 years ago.

This manual must be from some old dark century :-), since I have not seen those notations for years. The CCIR/ITU-R notation has been used for quite a few years, which divide the various modulations in three broad groups, amplitude modulation, angle modulation and pulse modulation. The amplitude modulation group contains the modulations starting with A, B, C, H, J and R (RR 270) and containing some of the commonest modulations e.g. A3E "AM", J3E "SSB" and C3F "TV". The angle modulation group contains such modulations as F3E "FM" and G3E phase modulation.

It isn't as much the problem at the transmit side, but the possibilities to
construct a simple demodulator in the TV set in every home that influenced
this decision.

A PLL to recover the carrier and a (pair of) DBM(s) to demodulate were not
exactly practical in those days.

Today it could have been done differently, of course. But migrating to
another standard is difficult. It always has to be considered that many
consider their ten year old TV set "a big investment that should work well
into the future".

>exactly practical in those days.

It is interesting to note that while PAL receivers in 1960's used
balanced demodulators to extract the R-Y and B-Y information, ordinary
envelope detection was used to convert the 30+ MHz IF to baseband.
Apparently due to the large amount of intermodulation in a simple
diode detector, the IF signal went through a frequency selective
diplexer, splitting the luma and chroma signal to different paths. The
luma path was demodulated with a diode detector to baseband video,
while the chroma path was mixed down with a diode mixer to 4.43 MHz.

As far as I know, the availability of DBM detector ICs driven by a
bandpass and hard limited carrier made the old approach redundant and
the 4.43 Mhz chroma subcarrier and 5.5 MHz sound subcarrier could be
taken after the DBM video demodulator.

So I guess that a single sideband reduced carrier TV standard (R3F)
would have been practical starting about mid 1970's when ICs with
sufficient gain and phase stability became available.

Paul

Did not the vestigial sideband come about due to something to do with
the original Channel One VHF Tx at Crystal Palace being DSB and there
wasn't going to be enough bandwidth in the rest of Band One for the
remaining channels?..

Seem to remember reading something about this in Practical TV in appx
1967 or thereabouts!...

Subject: ** FLEA at MIT ** The THIRD SUNDAY of Each Month APRIL thru OCTOBER in Cambridge MA

Spring has sprung...
and it is less than a month till the seasons first FLEA at MIT..

*** GREAT NEWS We again have full use of the garage for sellers !!!

Summary: Buy Sell SWAP Ham Radio Electronics Computers 9AM - 2PM

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday April 15th 2001
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20.00 or the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 33% discount. See the registration form
below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Yes, that should have been point 4... They were having enough trouble
building a BFO stable enough to reinject carrier for SSB voice transmission
at 14MHz; a receiver stable enough to deliver usable video at 60MHz would
have been out of the question...

>Today it could have been done differently, of course. But migrating to

Something we're running into again here in the States, with analog TV
transmissions theoretically ending in five years. Nobody believes it will
actually happen.

Interesting.

NTSC sets - all of them that I've seen diagrams of - have extracted the
chroma signal at baseband after the diode detector.

I did understand that the Crystal Palace transmitter was DSB - didn't that
cause some problems for receiver design? (having to consider that a set
would have to receive both DSB and VSB signals from other transmitters?)

>have been out of the question...

While SSB voice transmission can tolerate several Hertz frequency
error and SSB music transmission maybe a Hertz or two, with no need
for phase locking, since the ear is not very sensitive to phase,
demodulating a complex waveform, such as the video waveform, requires
that the carrier is inserted with exactly the right phase. A 180
degree phase error would produce a reverse video signal :-).

Maintaining an accurate phase across the whole network was previously
a big problem, a good evidence was the hue problems in early NTSC
transmissions.

Me too... what *is* being done frequently is to use a separate filter
and demod for the sound.
In those sets, the sound subcarrier is not taken from the video demod,
but a separate saw filter (with two response frequencies, one at the
video carrier IF frequency and one at the audio carrier IF frequency)
is used, followed by a nonlinear element (call it a detector or mixer
whatever you like) that produces the intercarrier sound frquency that
is then FM demodulated.

One could ask "why not simply use an FM IF strip at the audio carrier
IF frequency?". Good question. Because it would mean the whole receiver
would have to be on-frequency within about 20 KHz. With the intercarrier
system it can be off frequency by maybe half a MHz without influence
on the sound. So the set can be tuned for best video response.

I still have a case of brand new (OEM) front panel meters with the lights and sockets,etc.. for the SB220.

They are still in the original heath packaging with the original parts numbers on them.

I may also have the air variables and the tapped colis..

What are they worth these days?

this is quite unpleasant thread - you may not be aware that 80metre
band is 3500-4000kHz (or do you still say kilocycles?) while the 23cm
band is around 1296000kHz (1.296 kilomegacycles), quite a difference -
even in America!

I tried several dummies including one which is claimed to work up to
10GHz also one made by Bird

Interesting again. I've not seen any sets with that circuit here, though I will admit to not having seen any very recent diagrams. They do the same thing they do with the chroma; run a tap off to a 4.5MHz IF amp from somewhere after the video detector.

>One could ask "why not simply use an FM IF strip at the audio carrier

The very first sets sold in the U.S. had a split-sound circuit, with a completely separate IF chain for the audio. For the very reasons you cite, that system didn't last very long - it seemed to be gone by the late 1940s. One line of Sony TVs brought it back as an option in the late 1970s. (the TV had a switch, you could select split sound or intercarrier) The two monitoring demodulators we have at the TV station I work for also have split/intercarrier switches. Personally I can never tell the difference. (I suppose if we weren't careful to keep incidential phase modulation of the video carrier under control, it would be easier to tell...)

These days things are a lot more stable, I'll bet you could get away with split sound. Except that there are a few *stations* here in the States that have a VERY hard time keeping their transmitters on frequency. (some have been measured by DXers at as far as 70KHz off channel...)

What specifically are you trying to build? For the BPR 2000, there is
likely a custom back end IC at 455 kHz, but the rest of it is probably
bipolar discretes. Much of the low power consumption is acheived by
having the receiver asleep all the time. Schematics are likely
available through Motorola service. Search through the Mot web page
for pager and service and you might get a link.

The problem with intercarrier sound is that the presence of the video carrier is required in the mixdown process. This becomes quite obvious, when a simple video envelope detector is used.

The video carrier can be missing, if the signal is overmodulated or due to receiver misalignment when the peak white (typically in subtitles) drops the video carrier to 0 %. In this situation, the 3.5/5.5./6.0/5.5 MHz audio subcarrier is not generated, causing a severe audio interference.

>Except that there are a few *stations* here in the States that

At least in Band I VHF transmitters in Europe, the transmitters are not exactly on the nominal channel frequency, but spread out by some submultiples of the horizontal sync rate (it was previously in steps of fh/12, but I think the step has changed) to avoid some interference problems between stations. In this way, it is possible to guess which station is heard, when waiting for a Band I opening.

Are you sure that this 70 kHz is not some kind of similar deliberate offset ?

Paul

Yep. Basically the audio carrier disappears briefly 15,734.234 times a
second, and somewhat less briefly 60 times a second. (in the USA. Make
that 15,625 and 50 for Europe.)

I work at a TV station, but I still have a very hard time convincing my
colleagues that it's a VERY bad thing to allow the peak whites to exceed 120
IRE units. (the level that would result in negative visual power output if
it was *possible* to have negative power!)

>
>Are you sure that this 70 kHz is not some kind of similar deliberate
>offset ?

Yes.

The offset situation is much simpler in North America. There are only four
possible offsets: (these apply to all TV bands)

Minus: station is (exactly) 10KHz below the nominal frequency.
Zero: station is on the nominal frequency.
Plus: station is (exactly) 10KHz above the nominal frequency.
None: station is assigned to the nominal frequency but has a much
looser frequency tolerance. Depending on the channel, it could be
50KHz or more either side of the nominal frequency.

In the USA, "no" offset is assigned *only* to low-power stations. These stations hold a different type of license that can be easily discerned in government records. Such licenses used to be issued only to low-power relay transmitters. Since about 1985, they can now be issued also to stations that originate programming. But their power is still limited to 3KW ERP at VHF, 150KW at UHF. (until about 18 months ago, that limit was 100 watts transmitter output at VHF, 1KW transmitter output at UHF, and even today very few "low power" stations exceed those limits.)

Being 70KHz off the nominal frequency is most definitely *not* permitted for a 3000KW station in North America.

(unfortunately, that does make it much harder to tell what you're seeing during a Band I opening!)

That would be true in SECAM (but they use AM sound, Intercarrier is not
possible, and a separate IF is used.
In NTSC and PAL (at least in the normalized forms), the video modulation
is negative and the sync pulses (which I think you are referring to) are
sent at the maximal power, not the minimal.

>>Are you sure that this 70 kHz is not some kind of similar deliberate

What I find confusing is that the whole station is 70 KHz off-frequency but
the intercarrier distance is apparently correct. I thought that large TV
transmitters had separate chains and finals for vision and sound, with a
combiner to send both signals to a single antenna.

But maybe that has changed... is there no severe problem with intermod?
("weak" but still quite loud sound carrier appearing at the other side of
the vision carrier)

It is done in any decent (not low-budget) PAL TV and certainly in the
stereo sets. Our stereo system (I think not used in many other countries
than Germany and the Netherlands) uses two separate sound carriers, on
5.5 MHz and 5.74 MHz. The first one has the L+R signal (for compatability
reasons), the second is L-R or (very) sometimes "second language".

Apparently there is too much interference from the vision content and
color subcarrier (which is at 4.43 MHz) when all this is passed through
a single filter.

Other countries use NICAM, a system where the second carrier is modulated
with digitally encoded stereo sound. I don't know if they use the second
IF filter, may not be necessary for a digital system.

Often the traditional (state-owned) TV stations here have very good
stability of both the transmit frequency and the different frequencies
involved in the transmission itself (sync, color subcarrier etc). This
can for some stations (wellknown is ZDF and to a lesser extent BBC) even
be used as a frequency reference.

However, now most stations here are commercial and the quality of the
transmission is the very last thing they care about.

". . .I read a number of recently [1933] published papers, one of which was authored by Waldemar Poch and David Epstein, both in the RCA Research Department. This latter paper was a study of television receiver circuitry which was aimed at improving the 'resolution' or detail in a television picture and it prompted me to consider a method of transmitter operation which would double the detail in the horizontal direction of a television picture with no sacrifice in other picture qualities. The system concept was extremely simple but the execution required the design and construction of a device which I later called a 'vestigial sideband filter'. . ."

". . .The [prototype] assembly was forty feet in length and about ten feet wide. . ."

"Shortly after, a highly respected engineer from another company published a mathematical treatise which proved conclusively, by a batch of convoluted equations, that vestigial-sideband operation was not possible."

"On January 19, 1939, the Television Standards Committee of the Radio Manufacturers Association voted to recommend vestigial-sideband operation to the Federal Communications Commission. The vote would have been unanimous had the highly-placed RCA representative been brighter or better coached. It was slightly embarrassing to learn that he had unwittingly cast the negative vote. As a result of this expression of confidence by industry representatives, the system was included in the FCC Standards from the beginning of black-and-white television broadcasting in the United States. Consequently all television stations in the United States are now using vestigial-sideband transmission and the system is used throughout the world in all other countries where television broadcasting exists."

"RCA filed a patent application in my name on August 31, 1938, and United States Patent 2,214,041 issued on September 10, 1940."

Hi.

Does anyone out there know how to convert a 'Magnitude and Phase
Angle' to R+jX at ?

I plot the S11 curve ok on a smith chart but the calculations i have
only work with R+jX so i need to convert an s-parameter into R+jX

Anyone know the formula at all ?

Best Regards ... Clive

1982. Re: s-param to R+jX

Newsgroup: rec.radio.amateur.homebrew

Source record: 53778

Simple conversion of polar to rectangular coordinates. 11th grade trigonometry.

Easiest to do with a calculator that will do the conversion automatically or if you insist:

Where M = Magnitude
0 = Phase Angle

R = M cos 0
X = M sin 0

You overlooked something; s-parameters are normalized reflection coefficients and "simply" changing them from mag-phase to real-imaginary form doesn't give R + jX.

S-parameters are usually (but not always) specified in a 50 ohm system. If this is the case then s11 is the reflection coefficient (Gamma) of the load Z referenced to 50 ohm.

The impedance can be found by first converting Gamma to the Re-Im form as below then using:

Z = - 50 * (Gamma +1) / (Gamma - 1)

remembering that Gamma is complex. This is best done with a calculator that handles complex numbers.

1985. AM antena tuner or a notch filter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-03-30 20:12:07 UTC
From: Timothy Kellogg <tkellogg@wkyt.com>
Message-ID: <9a2ov7$5s4$1@nd.eastky.net>
Source record: 53783

I work at a Broadcast TV station Ch 27 (548 - 554 Mhz) and our mast also is home to 92.9 FM, Sprint & Verison cell phones, 2.4 Mhz mobile TV units, Pager service, etc. Needless to say the AM radio at my workbench is bathed in EM. I would like to listen to AM talk radio while at work but there is too much interference. I wanted some opinions as how to rectify the situation. I was first thinking of building a Notch filter tuned to our stations broadcast frequency but then thought that with all the other signals running around here that an Am band pass filter might be better (and perhaps wrapping the radio in aluminum foil to shield the IF from being overloaded). Just placing a diode across a multimeter (with the leads) gets me around 700 mv sitting on my bench. Any suggestions would be appreciated.

I am looking for the qst or a copy of the article in QST, May 1996 on pages
45-48
on modifying the Dentron MLA2500 to use a 4CX800 tube. I am trying to
decide on the way to go with the MLA2500. Of course a pair of drop-in
3cx400A7's would be fine, but I haven't found any for a decent price.
I will gladly pay for the magazine or a copy of the article.

Clearly the interference is coming from a "cast of thousands" so
notching is impractical. A couple of low-pass sections well shielded
may work BUT you will need a radio with an external ant input AND no
internal (i.e. ferrite rod or similar) ant.

741 should generate nice sine wave side tone. You may have something
wrong in the circuit or something really minor. 555 is working good,
but it generates square wave and it sounds quite rough on my ear,
however, is the simplest one.

IIRC, this may have been the case with the obsolete British 405 line
or the obsolete 819 line French system and with the current System L
used e.g. in France with positive video modulation.

All other systems use negative modulation and the synch pulses
corresponds to 100 % transmitter power. Thus, the carrier is _not_
interrupted during each line, otherwise,the intercarrier sound would
not work.

>The impedance can be found by first converting Gamma to the Re-Im form >as below
>then using:
>
>Z = - 50 * (Gamma +1) / (Gamma - 1)
>
>remembering that Gamma is complex. This is best done with a >calculator that
>handles complex numbers.

Yes assume it's referenced to 50R (Although i'd liked to know how to
reference it to other impedances).

The trouble is i'm in the learning stages and am no mathematician
unfortunately, so it would be really helpful if an example could be
shown at all ?

Heres some valid values ...

Mag Ang R jX

0.261 88.0 44.4 24.8
0.736 0.29 91.0 -141.0
0.943 2.0 1368.6 671.9

Now, there's obviously a divide in the formula as some very large R
values can be arrived at ...

Example using above 1st line of values (cos and sin work in radians)
...

R = Mag * cos(Ang * pi / 180)
jX = Mag * sin(Ang * pi / 180)

0.00911 = 0.261 * cos(88 * pi / 180)
0.26084 = 0.261 * sin(88 * pi / 180)

Now this is where i'm 'completely' lost :(....

>Z = - 50 * (Gamma + 1) / (Gamma - 1)

R and jX are 2 difference numbers, i guess this means it's a 'complex' number ????

I wonder where do i put the R value and where do i put the jX value ?

Thank you for any help with this ... Best Regards ... Clive

Yes, poorly worded on my part. Actually, the carrier is interrupted *more
than once* on each line (when the video is overmodulated), depending on the
video waveform. If one transmitted a solid white field of excessive
amplitude, the carrier would usually be gone, and would *reappear* 15,625
times a second. (and somewhat longer 50 times a second during vertical
sync) Obviously, such an extreme case is very rare.

This is a sign of gross incompetence, if such is allowed to happen. If
this goes on for a longer time, IMHO, the broadcasting authorities
should do something to such stations.

>If one transmitted a solid white field of excessive
>amplitude, the carrier would usually be gone, and would *reappear* 15,625
>times a second.

I have never observed this for large solid white fields, but over
here, it sometimes appears with white subtitles.

However, it is often possible to reduce this interference by changing
the channel fine tuning or reorienting the antenna. This would
suggest, that the interference is not necessary due to the transmitter
carrier power going to zero during subtitles, but rather some transfer
or reception problem, e.g. a multipath notch close to the carrier
frequency attenuating the video carrier, possibly into the noise floor
during peak white.

Absolutely. Actually, I've never seen that (a zero-carrier white field)
done on the air. With properly adjusted clipping amplifiers in the circuit,
it *can't* happen.

>I have never observed this for large solid white fields, but over
>here, it sometimes appears with white subtitles.

Yes, that's also the common situation here in the States. The subtitles are
small enough that they can be hard to see on the oscilloscope. Another case
where I sometimes see it is during live remote broadcasts (especially at
sporting events) where unexpectedly bright lights appear in the frame.

>However, it is often possible to reduce this interference by changing

I've seen it happen both ways. The latter one (where the station's
transmission is fine but multipath or improper tuning causes it) is far more
common.

We have also seen the phenomonon in the States where a highly-directional MW
station's antenna is more directional at the carrier than at the sidebands,
resulting in a badly overmodulated signal if you don't live in the lobe of
maximum radiation. (while the signal is perfect for those who live within
that lobe)

The MRX40 receiver was produced Steve Bornstein, K8IDN the president of our Columbus QRP Club. Did you want the Gerber files or artwork files? We have a meeting next Saturday, and I can ask him then if he doesn't show up on the reflector here before that. I don't believe he would have any problems with giving out the layout of the board.

EBay is the best place to buy varactors, IMHO. Many people (including Dan of Small Parts renown) sell them in lots of 50-100 for reasonable prices ($10-$20 or so).

Regardless of the diode type, you generally want to use parallel combinations of back-to-back varactor diodes to achieve the desired capacitance range and Q. It pays to have several dozen on hand.

The secret to keeping a MLA2500 alive and in good health is to make
sure your antenna stays in good condition and doesn't suddenly go
defective and unload the amp while it's on the air, and always monitor
the grid current while operating. Anytime you see grid current indicated
on the meter, STOP using the amp and investigate to see what went wrong.
Keeping the grids healthy is probably the most important single thing
you can do to keep the tubes in good shape. Those fragile grids won't
stand but a very few watts dissipation. Any visibile grid current while
operating on the air is too much, whatever the book says. When loaded
right (easily done) mine shows zero grid current at full output.
Mine 2500 still has the original tubes and they are still at full
output. I used it twice this week in a morning 75 meter group because of
rotten conditions. (I usually don't need an amp there.)

Do some serious scrounging for any of the older Hi-VHF Sennheiser "Wireless Microphone" receivers. A freind at a TV station gave several of us some older ones they were trashing 10 years ago. Several guys moded them with new crystasl (and on guy desinged and built a PLL synth" to operate at 136.nn. And several others just used the IF strip after the front end with Pro2004 scanners acting at the front end. Added a 10.7MHz IF tap and it worked like a champ. They ought to be farily common as they where very popular at TV station, but have bben replaced by (mostly) SOny/Azden/etc UHF versions.
I do not have a model number as I tossed the case after stripping the IF. Was about 55KHz wide, perfect for NOAA APT.
I now use a PCR1000, but still have the outboard IF "just in case".

A line of uninterruptable power supplies used Morse to signify error
conditions. They put a sticker with the appropriate codes on top, but if
you knew the code you didn't need the sticker.

recently i won a bid on ebay for a 100mHz txco with efc..
the seller didn't have much info other than pinouts..
the seller said that it needed 24vdc, and thought it was manufactured by Greenray..
i hooked it up and it works but i have a few questions..
i brought it up on a variable dc supply..
there was a linear relationship between input voltage and current draw until it flattened at about17 ma..
the knee was about 17 vdc..
plotting the p-p output, it flatened at 6.5 vac 100mHz..
this knee is at about 12.5vdc...
the question is: can the operating voltage of this unit be determined from this info without any doubt??..
the unit has no markings, it's about 2" by 2" and 1" thick..
solder sealed bathtub with 5 pins..
any facts or opinions appreciated..
tnx

So, you thought it important to post a reply to a piece of spam
that will *never* be read by the spammer, and you felt it necessary
to keep the crossposted list intact while doing it?

Ergo: "We don't really care about that, so go away."

2027. "4x3x5" bandpass filter for Mode J desense ROCKS!

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-02 00:41:56 UTC
From: nx7u@primenet.com
Message-ID: <3ac7c856.39731171@news.primenet.com>

Just got done testing my "4x3x5" 436MHz bandpass filter (1999 ARRL
Handbook p. 23.39, and numerous others in the past).
Boy it rocks, insertion loss 0.1dB and 3dB bandpass 8.5 MHz.
Rejection at 146MHz > 70dB, all as measured on my GR1710 vector
network analyzer.
No special construction, no silver plating.

Just the ticket for you FO-20/29 ops!

PS the hardest material to obtain is the 3" dia. copper pipe. I can
help if you're interested...
73,
Scott NX7U (soon to be reinstalling the mobile Mode J station)

2028. Re: s-param to R+jX

Clive...

The ARRL handbook has a much better overview of complex numbers, but in a nutshell, a complex number is a number that has both a 'real' and 'imaginary' component. In electronics, the real component is RESISTANCE, and the imaginary component REACTANCE.

This a complex number of the form R+jX specifies the resistive and reactive components. (j = sqrt(-1) ... don't try this on a calculator... that's why it's called an 'imaginary number'... wierd, eh? ;-)

However, the a+jb format doesn't always convey impedance information, it is also known as the 'rectangular' format of a complex number. The 'polar' format of a complex number is the magnitude/angle type of specification. Hence the conversion of your data that you were performing, ie

> Mag Ang R jX
> ----------
> 0.261 88.0 44.4 24.8
> 0.736 0.29 91.0 -141.0
> 0.943 2.0 1368.6 671.9
>
> Example using above 1st line of values (cos and sin work in radians)
>
> R = Mag * cos(Ang * pi / 180)
> jX = Mag * sin(Ang * pi / 180)
>
> 0.00911 = 0.261 * cos(88 * pi / 180)
> 0.26084 = 0.261 * sin(88 * pi / 180)

...was essentially correct, except that you are not calculating the impedance values R and X (more on that in a moment), but rather performing a polar->rectangular conversion. You have converted 0.261 ang 88.0 (polar) to 0.00911+j0.265084 (rectangular). This is not a waste of time, you need this for the next step....

"So, how the hell do I determine the impedances?" you ask... read on!

S11 is the input reflection coefficient of a network (or more commonly, the 'thing' you are studying). As Wes said, S11 is typically measured in a 50 ohm system. What this means in practice, is that we squirt a signal from a 50R signal generator into the device under test (DUT), and measure the magnitude and phase of the signal (if any) that is reflected back from the input port of the DUT. If the input impedance of the DUT was exactly 50R, then no signal would be reflected (all would be absorbed), and S11 would thus equal 0+j0.

If all of the signal was reflected (in phase), then S11 (also called gamma) = 1+j0. (or mag 1 ang 0 in polar speak)
If the signal was completely reflected out of phase, then S11 = -1+j0. (mag 1 ang 180)
If the signal was completely reflected 90 degrees out of phase, then S11 = 0+j1. (mag 1 ang 90)

...see how the polar representation gives you some insight as to what happens when a wave is incident on your DUT?

Transmission line theory gives us the following useful formula:

Zl = Zo[(1+gamma)/(1-gamma)]

Zo is the nominal test (system) impedance, as Wes said, 50R. Gamma is your friendly S11 value.

Now, plugging the numbers in to the equation is easy if you have a calculator capable of complex numbers, but tedious if not. Here's the tedious way....

From your polar->rectangular conversion, gamma = 0.00911+j0.26084.

Therefore, 1+gamma = 1.00911+j0.26084, and
1-gamma = 0.99089-j0.26084

There are several ways to proceed from here, but the easiest is to convert these back to polar format:

mag = sqrt(real^2 + complex^2)
ang = tan-1(complex / real)

For 1+gamma:
mag = 1.0423
ang = 14.4929 (degrees)

For 1-gamma:
mag = 1.0246
ang = -14.7479 (degrees)

Now (1+gamma)/(1-gamma) looks like: (1.0433 ang 14.7185) / (1.0257 ang 14.9771)

Divide the magnitudes and subtract the angles thus:

(1+gamma)/(1-gamma) = 1.0173 ang 29.2408

Convert this back to rectangular form (we're getting close!)...

1.0173 ang 29.2408 -> a+jb

a = 1.0173 * cos 29.2408
b = 1.0173 * sin 29.2408

ie 1.0173 ang 29.2408 = 0.8876 + j0.4969

THIS IS (1+gamma)/(1-gamma) ! Now all we have to do it multiply this number by the characteristic impedance (Zo), to give us:

Zl = 50 * (0.8876 + j0.4969)

(You asked about recalculating for a different characteristic impedance...? Simply change the 50 to whatever you want...)

Therefore Zl = 44.4 +j 24.8 ohms! (Voila! Just what we meant to arrive at!)

There you go! That's how you convert S11 data -> impedance information! :-)

Hope this helps,
James.
VK2XQF.

I'm reading this series of posts with interest. I've made several attempts to study two-port analysis in semi-great depth, but have always run aground when it came to converting the theoretical arguements into realistic applications. So far, everyone who's replied seems to have a practical grasp on at least one of the scattering parameters (S11). I am wondering if any of those who have responded to Clive's original post have had any formal study (i.e. actually sat down and learned the theoretical arguements behind s-params) with the s-parameters, and two-port network analysis (in particular)? If so, or even if you've just got a good grasp of both the theoretical and practical aspects of the analysis methods, are there any texts in particular that you could/would recommend? Like I said, I've got a pretty good idea of the theoretical mumbo-jumbo, but I'd like to see some nice applications of this stuff in the real world now.

Regards,
Pete

I would recommend the free info at:

http://www.tm.agilent.com/data/static/eng/tmo/Notes/interactive/an-95-1/

There is also some interactive stuff there.

H-P, before they split off the unpronouncable "Agilent", also published AN-95,
"S-Parameters... Circuit Analysis and Design" and AN-154, "S-Parameter Design."

These are long out-of-print but you might find them in a good technical library.

Motorola published AN-215A that doesn't speak of s-parameters but does discuss
amplifier design using y-parameters. See:

http://merchant.hibbertco.com/servlet/MtrlDeactServlet?page=5&s=&part=AN-215A

but hurry, it looks like this site is going away.

You can find a free cad program (Serenade) at:

http://www.ansoft.com/about/academics/sersv/index.cfm

There were some download problems at this site but maybe they've been fixed. If
not, email them and they might send it on CD.

This is a crippled version of a multi K$ program, that isn't just about s-parameters but can use them in circuit design.

I don't know what "real world" applications you are looking for but I can tell you that s-parameters are used every day to design and measure real circuits.

Have fun.

Hi Pete!

The best blend of theory and practice I have found is in:

Chris Bowick, "RF Circuit Design", published by H.W. Sams, Indianapolis,
1982.
ISBN: 0-7506-9946-9

It covers LC circuits, HF transistor models, amplifier design, filters
etc... a nice theoretical accompaniment to the ARRL handbook to explain
how a lot of the seeming leaps of faith are arrived at.

Cheers,
James VK2XQF :-)

Hi James.

Brilliant !!!

That's great. You ort to be a teacher if your not already one you know James.

I have borrowed a calculator of a friend that does deal with complex numbers (r and i) and sure enough, the formula from Wes works just fine.

Then what i really needed to do was to write a delphi routine to do the same so i needed to know exactly how to do it without having the built-in ability of dealing with complex numbers (which delphi does'nt have) ... ie, how to do it the tedious way :)

Things certainly seem to look easier once you find out how to go about it.

I agree Pete, it's certainly interesting.

>However, the a+jb format doesn't always convey impedance information, it is
>also known as the 'rectangular' format of a complex number. The 'polar'
>format of a complex number is the magnitude/angle type of specification.

When people refer to Rp and Xp i guess this means there referring to the 'polar' format (magnitude and phase) then ?

Also, if i assumed the exact same formula's apply to the S22 param's (output matching) would i be correct i wonder (i strongly suspect so) ?

I do have one question at present, James shows ...

Zl = Zo [(1 + gamma) / (1 - gamma)]

as the formula but Wes shows ...

Zl = -Zo [(gamma + 1) / (gamma - 1)]

I assume the above 2 formula's are fine, as the result is the same ... Wes flips the sign of the nominal impedance to recover the correct resultant sign so no problem there i guess.

Right, i'm off to try out my new found knowledge :)

Thanks again James, Wes, Pete and Bob ... it's 'very' much appreciated, it's got me onto the next stage (working out the stability factor (K)) :))

Regards to all ... Clive

As James said in his excellent post, just multiply by the characteristic impedance of the reference system.

S-parameters are derived from measurements that are normalized to the system impedance. Usually, they are measured using network analyzers that are very nearly perfect (mathematically anyway) 50 ohm sources and loads. This being the case, the results are usually normalized to 50 +j0.

This doesn't have to be however. For instance, if you want to normalize a load Z to the characteristic impedance of real (physical) transmission line then you use the complex line impedance. A real line always has some loss and this makes the line Z complex. Normally, this is not accounted for, but for precise work it is wise to consider the effect.

Careful here. Rp and Xp are usually used to express an impedance (really should
be an admittance) in parallel equivalent form; eg. 50 ohm *in parallel with*
100 ohm of capacitive reactance.

One should be just fine. As long as the amplifier isn't doing funny things
while disconnected, high isolation isn't an issue. If it is doing funny things,
eg, oscillating then you have another problem.

RELIEF FOR HAMS IN SIGHT
Amateurs gain reprieve from long-time clash with broadcasters

-from the Arizona State Union-Tribune, April 1, 2001

WASHINGTON, D.C.- Ask any Arizonan amateur radio operator what the most pressing problem on his frequencies is, and he will likely tell you it is the serious interference from shortwave broadcast stations in the 40 meter band that has grown progressively worse over the last two decades.

Yesterday, international broadcasters announced their intent to vacate the hams' frequencies in favor of another portion of the radio spectrum, bringing clear frequencies to hams for the first time in over forty-five years, the Bush administration reported.

Since the early- to mid-sixties, hams have had to endure increasing shortwave activity fueled by the Cold War, tensions between Cuba and the West, and the rise of governments in the Third World anxious to use radio to spread propaganda. Protected by international law, national broadcasters, religious programmers, and others have enjoyed virtually unlimited access to frequencies, cheap worldwide coverage, and operation at almost any power level they desired, creating an "elbow to elbow" situation for which no resolution was seen, given the squatters' stance taken by all parties involved.

Now, a major bloc of broadcasters has unilaterally proposed moving off of 40 meters onto a frequency band much less utilized now that it has been recently vacated by the military. The new band had been under the control of the United States Department of Defense since 1950, but has lied in fallow for years with the steady rise in the use of satellites for military communications. Broadcasters finalized an agreement with the Department to assume administration of the frequencies over the weekend.

The announcement came at a meeting of the International Federation of Shortwave Broadcasters (Fï¿½dï¿½ration Internationale de Stations de Onde Courte) in Geneva in late January. Of the 75 member countries of the organization, 61 have operations in the 40 meter band, meaning that the move away from 40 meters will constitute a mass exodus of signals which have hampered amateur radio stations for years. Ham radio operators stand to gain the most from the surprise announcement, but millions of shortwave listeners-- hobbyists with special receivers that can pick up the shortwave stations-- are also rejoicing at the prospect of clearer frequencies and more enjoyable reception.

The vote in favor of the move was 72 to 2, the two lone dissenting votes coming from Cuba and Iraq. Libyan representatives abstained from the voting.

"When you talk about surprise in the context of world policy, you imply that something has been discussed for a long, long time with what seemed like no possible solution, and that the solution was not foreseen by anybody, anywhere, at any time in the next five years. This is definitely an astonishing surprise," declared Warren Kruger, a diplomat and regulatory commissioner with the State Department in Brussels who was involved in recent restructuring of shortwave allocations for the European Union. He said that prior to the announcement, the best scenario envisioned by US and European policymakers was the remote possibility of the question of 40 meter broadcast interference appearing on the agenda for the World Radiocommunication Conference (WRC) in 2003. "Even then, it was doubtful whether the issue would have made it past the committees onto the general floor. It just wasn't seen as pressing enough in the face of other, stickier matters," he said.

Under the proposed move, shortwave stations from the 61 nations would vacate the 7100-7300 kilohertz band between now and the end of 2006. The majority would move to a band between 7325 and 7490 kilohertz, with some others scattering to several frequencies above and below that band. According to Kruger, the major consideration was the acquisition of frequencies with characteristics similar to the 40 meter band in terms of range and time of day when the best reception was possible. Evidently, the new frequency band is satisfactory to the stations involved on all accounts.

Other officials blindsided by the shotgun announcement were from both the Federal Communications Commission (FCC) and the national association for amateur radio in the US, the American Radio Relay League (ARRL). LaVonne Burke, head of the FCC field office near Quantico, Virginia, expressed shock and confusion over the Geneva statement. "We didn't even have representatives there, thinking that there wouldn't be any significant movement coming out of Geneva. All of our attention was fixed on 2003, frankly." In Newington, Connecticut, an ARRL spokesman struck a skeptical tone. "We need to be very cautious in our response to this unilateral agreement," he said. "What effect will it really have? Does it leave us more or less susceptible to other actions aimed at reducing our frequency allocations? All these questions remain unanswered and our vigilance cannot diminish at this time just because a group of broadcasters decide to up and move off a frequency."

Hailing the agreement as "monumental, a gift from heaven," well-known Arizona ham Clyde "Skip" Butler declared the dawn of a 21st century era for ham radio. "We never thought we would see this day. It is the answer to our dreams and I can't tell you how exciting and how promising this is to us. It's like being told you've just won the lottery." Another Flagstaff-area amateur who identified himself as "John L.", explained what this meant to him. "My buddies and I have met on 40 meters every night for the last eighteen years, and every single one of those nights,

it has been a struggle to find a clear spot to set up our transmitters. If it wasn't the howling of Radio Moscow, it was the splatter from one of those darned religious stations that completely wiped out the band. We've hoped for years that the ARRL could somehow kick them out and give us some relief. Man, I can't tell you how nice it will be without having to worry about [the broadcasters] anymore. I can't wait."

Amazingly, not all amateurs are welcoming the less-cluttered future of 40 meters with open arms. In Ohio, a demonstration is planned at the Dayton ham convention in May, the largest in the country. Organized by a group of ham traditionalists, the demonstration will take the form of an 80-vehicle-long caravan which will parade through the city carrying signs and placards and protesting on a number of ham frequencies as they progress. An unidentified member of the protest stated, "Generations of hams have literally grown up with having to dodge interference on 40. It made us better operators, having to use operating saavy to survive in between Radio Moscow and Voice of Free China. This makes us look like wimps who have to be pandered to and who can't stand a little bit of rough going. Our mission is to fight for ham ingenuity and for the reputation of hams everywhere."

Other amateurs reserved their excitement for other reasons. In phone conversations with this reporter, several hams expressed concern that the elevation of amateur radio to exclusive use of the 40 meter band could endanger their hold on other, nearby frequencies that are being eyed by a number of other services who have a new-found, increased appetite for spectrum space for Internet and communication services. They said also that new hams entering the hobby through a streamlined FCC licensing process that has been generally viewed as easier and less demanding would not appreciate their frequency privileges without the added challenge of having to confront shortwave interference.

Within the next five years, whether it is good or bad for the hobby, it will undoubtedly be easier and more pleasant to tune the 40 meter band and converse with other radio aficionados. While some will enjoy the arrangement, others will bemoan the loss of yet another ham tradition. Whatever the outcome, hams will be left to craft a response to the sudden and very unexpected windfall.

Sure, just be sure to stay above the existing voltage rating.

If you can find one that is not too lossey at the frequency one is
fine. The inpedance and gain is usually low enough that you do not have
to worry.

> Specifically, can I replace a 30uf 300v with a 30uf 400v?

The dielectric in an aluminum electrolytic capacitor is the anodic oxide film. In the absence of a polarizing voltage, this oxide film gradually hydrolyzes, decreasing the voltage rating of the capacitor. The effect is not uniform across the capacitor foil, however, so the capacitance, which should increase if the decrease in film thickness were uniform, may actually change the total capacitance very little. This gradual hydrolysis is one factor behind electrolytic capacitor aging, another being the evaporation of the electrolyte. Thus capacitors that have been left unused for a while need to be reformed, the process where the oxide film repairs itself and regrows to the original thickness in the presence of the proer polarizing voltage.

When an electrolytic capacitor with a higher voltage rating than is needed is used in a lower voltage circuit, the result is that it gradually becomes rated at the lower voltage. It is typical to derate an aluminum electrolytic capacitor as much as 30 percent. But going much over this is wasting money and may cause a significant change in capacitance.

In this case, using a 400 volt electrolytic in a 300 volt circuit is fine. But I would not consider using a 400 volt capacitor in a 100 volt circuit.

Clive,

Many thanks for the kind comments, pleased to be able to help! :-)

In answer to your question...

> ...what if the characteristic impedance is not purely resistive...

Hmm... I'm not sure about the practical implications (from a measurement perspective) of this scenario, but from a theoretical viewpoint you are correct, simply perform: Zl = (R + jX) * (0.8876 + j0.4969)

The good ol' complex calculator will help here, but the 'tedious' methods of complex multiplication are as follows:

Option 1.

- Convert the rectangular format to polar.
- Multiply the magnitudes, and add the angles to arrive at the answer (polar format).
- If you need to, convert the polar form back to rectangular.

One thing to be aware of: All of this polar<->rectangular conversion carries a penalty in terms of accumulating rounding errors, but these errors will never amount to anything of practical significance. (I just thought I'd mention it if you observe your calculator and delphi answers differing in the 5th decimal place... :-)

Option 2.

- Expanding the expression algebraically, we get:

Zl = [R * (0.8876 + j0.4969)] + [jX * (0.8876 + j0.4969)]
= 0.8876R + jR0.4969 + jX0.8876 +jjX0.4969

OK, here comes the wierd bit... :-)
j is defined as the sqrt(-1)... therefore, j * j must equal -1... applying this and collecting like terms...

Zl = 0.8876R + jR0.4969 + jX0.8876 - X0.4969
= (0.8876R - X0.4969) + j(R0.4969 + X0.8876)

Tada!
Option 1 is probably nicer... ;-)

Have fun, and keep Mr. Rollet's stability factor (K) > 1!

Cheers,
James.

P.S. Rp and Xp are usually the 'parallel equivalent' impedances of a network. i.e. A network consisting of a resistive and a reactive element in series (call them Rs and Xs) can also be modelled as a resistance Rp in parallel with a reactance Xp (via some formula buried here in a pile of paper somewhere...!)

marvin rosen wrote:

> why were loop sticks used over variable capacitors to tune a car radio?

Auto radios were designed with different goals in mind. They are used in a dirty environment (out doors, in a dusty dirty setting, greatly varying temperture and humidity, etc). Any moving contact is a source of trouble (volume controls had to be sealed units, and even then prone to noise). Inductive tuning with sliding slugs is less trouble prone. Other considerations were that auto radios would be used in fringe areas as well as near strong stations. For the former reason it was customary to include at least one stage of RF amplification, where radios used in the home often had none. Because between cities there might be several stations close to the same frequency that could be received, more selectivity in the IF stages were required. So auto sets often had TWO if stages instead of the one used in home sets. Also a lower IF frequency was used, often 262 KHZ instead of the 455 KHZ commonly found in home sets. Late tube model car radios used a special set of tubes that could operate with only 13 volts on the plates. These radios didn't need a HV vibrator power supply. Since it would require many tubes in parallel to develop enough power to drive a speaker with only 13 volts on the plates, a power transistor was used for this purpose. (remember the DS501 doorknob transistor?) The driver tube was usually a power tetrode, using a 'space charge' grid. In this type of tube the first grid is connected to the B+ supply and the second grid is the control grid. This arangement increases emission without increasing heater current requirements.

Probably more than you wanted to know......

Check ot the Harris broadcast website. The current transmitters are
built to handle 110 kHz bandwidth. mono or Stereo, SAP, and a lower
quality audio signal for the station's own use. Similar to SCA) Do a
search on BTSC audio and you'll see that the current tv's are not 25 Khz
audio. And I don't care what you call it, but the FCC called it
Vestigial sideband on all the documents and I consider them the
authority, not someone I've never met.

By the way, I no longer work on such narrow band equipment. The
company I work for builds receivers with 20 Mhz IF's, and NASA doesn't
launch without our equipment.

If its an RF application for UHF or higher, then lead inductance can be a problem. For other apps with an SOIC get a good low wattage soldering iron and good magnifying lamp etc.

Believe some of the Radio mags had artcles on ising SOIC packages.

Haven't tried it yet myself, but hope to in the near future.

Reminds me of a computer controller I was programming at Gould. This was an
8 port serial controller that could do EVERYTHING (async, bisync, sdlc, etc).
The hw designers put a single led on it to indicate status. But someone
wanted to know if the unit passed the self test, and if not what went wrong.
Guess how I multiplexed all that info on one led? (Why is that led blinking
in a crazy way?)

Hi All,
I have the following equipment for sale:

1. Kenwood SP-31 speaker. Very Nice condition, a few marks here and there. Overall, a solid 8+. Price $55.00 + shipping.

2. Brand New Cardwell Air Variable Capacitor Model 154-16-1 30-240 pF @ 4500 VDC. Item is unused. Price $50.00 + shipping.

3. Unbuilt Dick Edwards Electronics Kit - Bench Power Suply. Adjustable voltage 1.3-30 V and adjustable current 0-1 A with current limiting. Kit is unbuilt and complete with all parts, cabinet and transformer. Price $50.00 + shipping.

4. Kintronic Laboratories Tank Coil. 27 uH at 10 RF Amps!! Well built, edge-wound inductor with silver tapping clamps - Built like a TANK. Price $75.00 + shipping (taps included).

Photos available upon request.

The W1FB series of homebrew books have a lot to offer. I think they
are ARRL publications.

Try:

http://www.arrl.org/catalog/?category=Circuit+Design&words=&SelectCategory.x=9&SelectCategory.y=10

If you have specific questions, I would be happy to "Elmer" off the

Hi all. I'm a college student who is completely new to amateur radio. I have checked out a couple of books to get me started, but I still have very little knowlege of the amateur radio world. I have a general knowlege of electronics and I was hoping to build my own simple receiver. My questions are, 1) is it possible? 2) what books would you recomend for beginners who know nothing about radio and are looking to get started? 3) are there any books or online resources that will help those who are looking to build their own simple shack? Any help would be appreciated.

Thanks

Hi James.

>Many thanks for the kind comments, pleased to be able to help! :-)

Well deserved, i'm sure all would agree :)

I'll try your option 1, you certainly seem to have a good grasp of
things !

>One thing to be aware of: All of this polar<->rectangular conversion carries
>a penalty in terms of accumulating rounding errors, but these errors will
>never amount to anything of practical significance. (I just thought I'd
>mention it if you observe your calculator and delphi answers differing in
>the 5th decimal place... :-)

yes that did come to mind as soon as i saw the number of calculations
but the calculator has 10-digit resolution and delphi has somewhat
more so no problem at all there. Real components are usually only 1%
at best anyway.

>P.S. Rp and Xp are usually the 'parallel equivalent' impedances of a
>network. i.e. A network consisting of a resistive and a reactive element
>in series (call them Rs and Xs) can also be modelled as a resistance Rp in
>parallel with a reactance Xp (via some formula buried here in a pile of
>paper somewhere...!)

Well no need to go any further (for now :)) ... i have plenty to go on
now.

I download the Serenade program Wes mentioned, looks like a very nice
piece of cad software, especially after using Puff but i still like to
know how things are done mathematically.

Once again, thank you all for your great help, excellent !

Right, now to try things out on a real circuit.

Best Regards ... Clive

Hi.
My name's Josh. I'm also a college student, new to amateur radio design, although I have been in the fielf and held a licesnse for some years now. I have always enjoyed radio, but never knew how to design it. I am just scraping the tip of the iceberg now when it comes to design analysis. As an electrical engineering student, I was disappointed to find only 2 classes here at WSU (Washington State) that dealt with RF, only 1 with design. I found that this is common, with true RF design being taught usually at a master's level.
So, I was frustrated, as usual, that I couldn't obtain the knowledge that I was after. Since I took on the exact same challenge you have of making a receiver only a few weeks ago, I have met several key people right here in this group who are true masters at radio design. Chances are any question you have will much more thouroughly and quickly be answered here at first than in a book. Of course, it isn't a substitute for a good book, but you know how books are sometimes dead ends when they just don't explain something well enough.

Here are some books that I have purchased recently that were recommended by some of the pros. All are TOP NOTCH, and worthy of notice.

-- Introduction to Radio Frequency Design by Wes Hayward, W7ZOI
[A little on the math intensive side. I wasn't ready for this quite yet, but its good to have for when I do want to challenge myself further. Comes with circuit analysis software.]
(www.amazon.com)

-- Solid State Design for the Radio Amateur, also by Wes Hayward
[I'm told a great book, full of practical circuits and not a ton of theory. I have not received it yet.]
(http://www.arrl.org/catalog/index.php3?category=Circuit+Design)

-- The Electronics of Radio, by David B. Rutledge
[Very cool book. The author is a Harvard professor who teaches the principles of basic electronics and radio, while using a popular low power transciever, the Wilderness NorCal 40A as a model for the principles discussed in the book. I didn't get the kit because I had just spent all my money on books. I talked to the manufacturer, who doesn't offer a student discount. So, maybe some day. This book also comes with circuit analysis software.]
(http://www.arrl.org/catalog/index.php3?category=Circuit+Design or
from the publisher:

http://www.cup.org/ObjectBuilder/ObjectBuilder.iwx?ProcessName=ProductPage&Merchant_Id=1&product_id=0-521-64645-6&origin=search&searchField=ALL&searchString=The%20Electronics%20of%20Radio)

-- RF Circuit Design by Chris Bowick
[Another book with lots of math formulas and smith charts. I have not studyed it in detail yet. I was told not to think of starting radio design without owning it, but warning: it is very intense.]
(www.amazon.com)

Well, I hope this helps. Let me know how it goes for you. I'm almost at the exact same place you are. Good luck.

Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

I have a very limited personal stock of NOS Metal can type caps for sale, not cheap at $17.50 each but they have all been tested and run up past their rated voltages with no problems. Small and larger size units, not a large amount left, but I have enough to help a batch of people.

I also have the original multi section NOS paper body type used in classic 5 tube am/fm radios for similar prices. I hand tested each cap when I purchased a closing wherehouse stock last month. Any cap sold will tested and operated at the full rated voltage plus before shipping.

Email me direct if your interested...

These are Original NOS Metal Can Sprague, Pyramid and Mallory brand/type caps in the slim and standard size packages.

cheers and thanks

Hi, I opened the case and found that there is a can capacitor in there. Does anyone know where I can find a 3 lead 30 MFD 350v, 30 MFD 350v, 300 MFD 25v capacitor? Can I replace it with individual components? If I can, how would I connect the three new ones? There are three leads on the bottom of the can with a mark next to each lead the matches the mark next to the value on the case. Thanks again,
Mike

Yes definitely.

2) what books would you recomend

The 'ARRL Handbook' and 'Solid State Design for the Radio Amateur' both
from the ARRL.

3) are there any books or online resources

You will find some info and some links on my webpage (URL below).

Mike,

There are some sources of can caps, but they're getting very spendy.
Amateur Electronic Supply, RF Parts Company, Surplus Sales of Neb.,
and Fair Radio Sales all come to mind. The capacitance values are
not as critical as you might think, which will expand your horizons
somewhat. For example, you can probably do just fine with caps up
to 47 uF in place of your original 30 uF, and anything from 250 to
500 uF in place of the original 300 uF.

If you're not concerned with the equipment looking original inside,
then you can certainly use individual axial-lead caps in place of the
original can-type cap. This will almost surely be the cheaper route
as far as parts cost.

SAFETY WARNINGS concerning electrolytic caps:
1. Be sure that the voltage ratings on your replacement cap meet or
exceed the ratings of the original cap. Electrolytic caps can
explode violently if their voltage rating is exceeded.
2. Be sure to observe correct (+) and (-) polarity when you install
new caps. Electrolytic caps can explode violently if they are
connected backwards.

As for how to connect them, a look at the schematic will explain how
they're connected electrically. Can-type caps typically use the can
itself as a common ground for all sections, and the can is normally
connected to ground (screwed, riveted, or soldered to the chassis
itself in most cases). Some cans have a paper or plastic coating to
insulate the can, and may be mounted on an insulated footing to float
the can above the chassis. In these cases, the can is NOT ground, and
you'll have to observe that when you replace it. Match up the square,
triangle, and semicircle icons with the markings on the old can, then
connect your new caps as such. There are often some components mounted

off of the can cap's solder lugs (bleeder resistors, etc). In place of the cap terminals, you can use terminal strips. The "gotcha" is often a lack of space to mount individual caps under the chassis. In some cases, I've mounted them on pieces of perf board standing upright above the chassis in the space formerly occupied by the can cap. You may have to get "creative".

It's a shame we can't just walk down to the corner TV shop and buy any electroltytic cap right off the shelf like we used to...

2071. has anyone made a Rayovac charger run on 12 volts?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-03 19:43:40 UTC
From: mcalhoun@ksu.edu
Message-ID: <9ad95c$dii@unix2.cc.ksu.edu>
Source record: 53667

I'd like to "cobble" the Rayovac PS3 battery charger (charges NiCd's, NiMh's, and Rayovac "Rechargeable Alkalines", of which I use a whole bunch) to operate on 12 volts instead of 120-volts AC so I can recharge my batteries while camping. Rayovac told me to NOT use a simple inverter because the transformer in the PS3 really wants a good sinewave.

Has anyone determined how to do this?

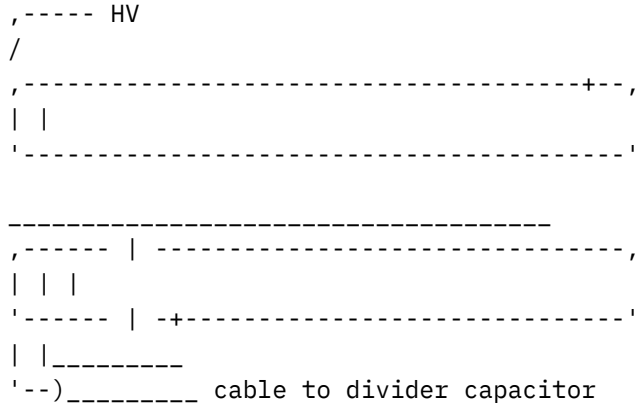
2075. neutralizing capacitor - two discs with adjustable spacing

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-03 20:23:14 UTC
From: Winfield Hill <hill@rowland.org>
Message-ID: <3ACA3132.47D8DA79@rowland.org>
Source record: 53669
Cross-posted to:
sci.electronics.design,sci.electronics.components,rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors,rec.radio.swap

Hello Gang,

My AoE coauthor, Paul Horowitz, is looking for an old
classic RF transmitter neutralizing capacitor - some
of you know what I mean, the ones with two plates
made from large discs, with one adjustable to set
the spacing. I had a nice one with 4" diameter discs,
but I modified it for a 20kV RF divider.



Yes, better done other ways, but that's another story.

If anyone has one he'd be willing to part with (for
a good price, natch) or knows where one might be had,
we'd really appreciate it. These caps are very good
pedagogically speaking, and one will make an excellent
addition to my friend's teacher's bag of show-and-tell
stuff for his students. They are virtually the ideal
textbook capacitor, the type one never sees in real
life these days!

Thanks,
- Win

goto

http://www.arrl.org

ARRL has a lot of great books

> 3) are there any books or online resources
> that will help those who are looking to build their own simple shack?
> Any help would be appreciated.
>
> Thanks

I was exactly where you are 1 1/2 years ago and these sites and a lot of
soldering have got me a shack with all tube based gear. I've got an
80m/40m 75watt HB transmitter based on a design from a a 1959 QST article
and a tube receiver based on a design I got from Harry's Home Brew web
page. plus half a dozen QRP tube transmitters and receivers based on
design that I got from various web pages. They all work great (after a lot

of trouble shooting). Good Luck

Message-ID: <9adeve$2se$1@nd.eastky.net>
Source record: 53689

Looking for a 100 pin extender bord (or just a piece of perf board with the proper connector) These are probably the standard (old) 100 pin connector (S-100?) size. The pin out is 50 conections per side, the pins (contact points) are 1/8 inch wide, 7/16 long, with 1/16 inch spacing between the "pins". The width of the connector end is 5 1/8 inch with the contacts starting 1/16 inch from the sides. Across the width of the connnector (which by the way is just etched on the edge of the card) the distance.

To be fair, Serenade is a different type of tool, mostly used for different jobs. You can't handle striplines as easily in SPICE, or get the same range of plottable input/output parameters, but on the other hand you can't do time-dependent transient analysis with Serenade (or rather, Harmonica). There is an area of overlap where either tool is usable, but in reality you need both.

The free downloadable student version of Serenade has now replaced ARRL Radio Designer (which is no longer available) and will do much more, including nonlinear analysis of harmonic generation and intermodulation. It includes circuit drawing and schematic capture - and at long last, device libraries - so there is no more messing about with ASCII netlists. Serenade is actually a combination of two different tools: Harmonica which is the circuit analysis program; and Symphony which is more oriented to system analysis at the block-diagram level.

A very good free SPICE implementation is SIMetrix, downloadable from www.newburytech.co.uk Newbury Technology are very happy for hams to download the program and use it. The drawing and schematic features are all smoothly implemented, and so are the output graphics, so you can work at the graphics level and don't need to see anything of the underlying SPICE netlists. The demo version is fully functional except for a size limit on circuit complexity, which I haven't found troublesome so far.

It looks like the software manufacturers are changing their policies and making the free demo versions much more powerful than before. This is very much to the benefit of us amateurs!

700 mv sitting on your bench? Maybe you should think about where you
work. But then again, I don't know enough about RF to know if this is
too much exposure.

First, you have two choices regarding the old can capacitor: You can either leave it in place disconnected, or restuff new capacitors inside of the can replacing the old innards. If this is any sort of vintage BA set, having a gaping hole where the can is supposed to go is a cosmetic and restoration no-no.

You cannot parallel the new capacitors with the old ones, however. It is fairly simple to add a tie strip or two under chassis to provide mounting points for the new capacitors. Most modern caps will be a fraction of the size of the vintage cap in the set.

The smaller 300m/25v cap was probably across the audio tube cathode, and it is often just as easy to mount the new cathode bypass right at the audio tube socket. You will find other convenient common tie points under the chassis where the higher voltage caps could also be installed, no doubt.

2085. Looking for a 100 pin extender board (whole message)

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-03 22:56:03 UTC
From: Timothy Kellogg <tkellogg@wkyt.com>
Message-ID: <9adk1s$572$1@nd.eastky.net>
Source record: 53690

Sorry about the dual post - the first one got sent too soon.

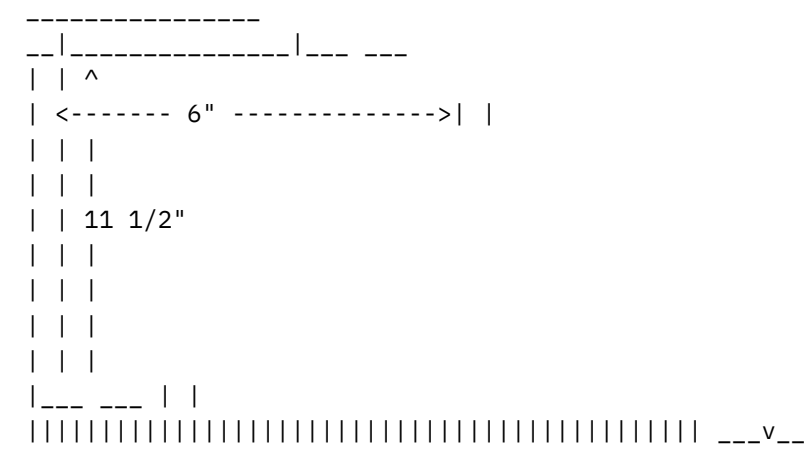
Looking for a 100 pin extender board (or just a piece of perf board with the proper connector) These are probably the standard (old) 100 pin connector
(S-100?) size. The pin out is 50 connections per side, the pins (contact points) are 1/8 inch wide, 7/16 long, with 1/16 inch spacing between the "pins". The width of the connector end is 5 1/8 inch with the contacts starting 1/16 inch from the sides. Across the width of the connector (which by the way, is just etched on the edge of the card) is 5".

The whole board is about 12" long and has a 50 pin female connector on the "top" so that the circuit card under test can be "extended" from the circuit and worked on/ tested while extended. (this means the pins on the bottom of the card are electrically connected to the similar pin on the top of the card)

I am using this to troubleshoot a Harris Facility Controller 9165 (part of a 9100 system). The company no longer supports this equipment - if you have anything like this or have any suggestions, please drop me a line.

I have an extension card that with the proper connections but the card is 7" wide and I'd rather not "trim" it to fit because as soon as I do I'm sure the equipment it goes to will break and then I'll be no better off.

Here is my attempt to diagram the board using ASCII (might look better in Courier font but don't quote me)



connector is
5 1/8 inch wide

The board is probably 1/16" thick

2086. Regency Polaris MT5500

Source record: 53681

Folks---

I recently acquired a Regency Polaris MT5500 raido. I was told the machine could do 137--153 MHz, or something like that. Does anyone happen to have a manual and/or schematic for this unit, or know where I can find one? The manual would be preferable, however a schematic would be a definite bonus.

Thanks,

Henry C. Gernhardt, III

Absolutly possible! And really not that hard. Get a copy of the ARRL handbook (check a library). Read it and you'll be in a whole new world!

Have you found one yet? I have one of those monsters, must be
about 1/4" plates est diam 2-3" or so. Believe it was made by B&W
what are they worth. Stands pretty high also, fits' the look of the
times ie 813's.

Exactly, and indeed both Paul and I have had some very
nice air capacitors made in the machine shop, however
the original item, complete with the threaded ceramic
standoff, is very much to be preferred for a teaching
tool. Consider, the elegant engineering and earnest
craftsmanship of that early great old era can live on,
newly minted, by becoming ingrained into the new mind
of a young Harvard student, plus all the students from
other schools who come to Cambridge to take Physics 123
each summertime.

So someone, please, let's find one of those old beauties
for the cause. And for the Bud. Ribbit.

Thanks,
- Win

Will TRADE TUBES for EICO 667 manual copy!
Am deseperate. Need Instructions for EICO 667 tube tester soon.
I will trade 10 or+ GOOD 6v6 addio output tubes. Good tested pulls in
boxes.
Tested in Superior TR-11 tester. Reason: I shipped my Eico 667 w/roll
chart,
extra data books etc. to a Man in NY. He can't figure out how to operate
it.
He thinks it is broken. I know it is not by his description. I can not
tell
him how to use it, unless it is infront of me. I need a partial manual
(instruction section),
to send him. I will be very generous in tube trade.
Please consider this offer. Even scanned image files of instructions
will do it for him.

Thanks for reading,
John Williams

Alex: Get lots of books -- don't just depend on one. Different authors will have different ways of explaining things -- if you get stuck with one, switch to another. You need to be building a small library.

You can build simple a simple receiver, but start out slow. I built a few simple transmitters before I took on a receiver project.

You'll see lots of designs for simple receivers that use IC chips. If I were you I'd look for designs using discrete transistors. I think you'll come away with a better educational experience.

Good luck. Hang in there. 73 Bill CU2JL N2CQR

Hi Alex,

of course it is possible to build your own receiver, and maybe you get
interested enough to pass the test for a amateur radio license later...

To get some hints, do a search for 'homebrew' at
http://www.radio-portal.org
in the category "Receivers".

Such a search also works for other categories, like "Antennas" or
"Transceivers", for example.

Best Regards,
Willi, DJ6JZ

From: k4wwd@arrl.net
Message-ID: <9afd6m$al9$1@news.netmar.com>
Source record: 53600

This subject has already been out for a while. I am the proud new owner of
a
vintage HW-8 with the Main tuning capacitor plates "GONE"!!! I have come
across
some references to some homebrewers refitting/gluing the plates back in
place.
My plates are GONE. Does anyone out there know the original configuration of
the Heath cap as delivered from the factory? I have heard speculation that
it
was a 365 pF variable with every other plate removed. Correct? B.S. ??
Does anyone out there know a source of supply for this component? Anybody
out
there want to part with an extra variable cap? I am thinking of
"transplanting" some
plates from another capacitor, but I have never seen one intact. Perhaps one
of you out there could describe the number and spacing of the plates on the
rotor section for me? I just do not know what it is supposed to look like!

Thanks for all your help.......73, Bill -K4WWD

Whatsamatta Psycho, you don't like products that have a useful life
of more than two or three years. Is that because your personal skill
set is incapable of producing an innovative product having a useful
service life of over one-hundred years, as many of those products
with the claw feet, artistic scrolls, and gold-leaf trim have?

If you prefer the quality of products manufactured today with a
useful service life of 3-years, incapapable of being cost effectively
repaired, then destined to being ground up for scrap, it is likely
because you yourself are personally incapable of designing or
manufacturing anything superior -- as those who have preceded you
(and me) clearly were.

Sadly, it appears the technology with which we are familiar can
be characterized as producing ONLY high-performance, low-quality,
short-lived, throw-away specialty items. Items of this type have
only a very limited value to the needs of our core infrastructure.

By contrast, that claw-footed punch press, bathtub, and decorative
turbine housing existed long before high-tech throwaway products, and
some are likely to remain in service long after many of today's "hot"
items are just a fading memory. This is because beyond the basic
utility of such low-tech items, the design skill and craftsmanship
that produced them far exceeded that of most of today's over-
specialized, high-tech design types who, without the help of
a computer, design handbook, and product catalog, are incapable
of designing very much of anything yet alone add decorative
flourishes as as an indication of the designer's pride in his
accomplishment.

Hi Win,

I recall two firms making neutralizing capacitors.

James Millen in Malden, MA made the disk style units precisely as you describe. Unfortunely as you no doubt know, Millen has been out of business for some years, but if you prowl around surplus dealers in the Malden vicinity, you may be able to find one or two. The Millen part number for the 2" diameter disk neutralizing capacitor is No. 15011. (You might also want to have someone check the MIT ham radio flea market, since I recall one dealer there who regularly has transmitter type variable capacitors for sale.)

Another potential source would be E.F. Johnson Company in Waseca, Minnesota. (They MAY still be in business.) Johnson made the Type G neutralizing capacitor. By contrast with the Millen product, Type G consisted of two coaxial cylinders with a screw adjustment that determined the degree of penetration that the smaller cylinder made into the larger one.

National Radio (famious for their HRO series receivers) was also located in Malden and made a component line, and although they did produce a line of variable capacitors, I don't recall them offering any neutralizing capacitors.

Win, for whatever it's worth, neutralizing capacitors of the above type were generally associated with triode final amplifiers whose popularity declined rapidly shortly after WWII. As you know, triodes exhibit considerably higher plate-to-grid capacitance than do the tetrodes that rapidly replace them (at least in ham use). Becuase of the shielding effect of the screen grid, plate-to-control-grid capacitance, tetrode r.f. amplifiers required very little neutralization, hence the market for neutralizing capacitors just about completely died after a huge increase in the use of tetrode final amplifiers circa 1950 or so.

I received by first ham license while in middle-school (1952). My second rig used a donated Taylor 100TH triode, hence I at one time owned a Millen neutralizing capacitor. Sadly, that capacitor went with the rig at the time I disposed of it.

Good luck with your search.

Harry C.

p.s. Both the Millen and National products are depicted in the catalog sheets bound as part of the ARRL 1956 "Radio Amateur's Handbook."

That is economically sound, for any technology that changes rapidly. As you mention, infrastructure technology changes less slowly, and should be built to last longer, but even that is changing relatively rapidly (on the order of decades rather than centuries).

Of course, some technologies change slowly, and these items should be built to last.

We are not in the two way radio business. We build customized, modular
telemetry equipment. To the customers needs. Not what some old fart
thinks they can make the customer take. Whatever band, modulation type,
and other special needs they may have. We also design and build
complete tracking systems. NOAA uses a special system we built to track
their weather satellites. I could go on, but you'll still tell me I'm
wrong, so I'll save my time.

The IF's are at 70 Mhz, and up to 20 Mhz wide. It's in top of the line
telemetry equipment that you wouldn't understand. And in Telemetry you
use either 20, or 70 Mhz IF's so the signal can be recorded on wide band
logging equipment.

OUR CUSTOMERS WOULD LAUGH IF WE OFFERED RECEIVERS WITH A 21.4 Mhz IF!

They connect equipment to the IF outputs to do additional signal
processing with them.

You had a patent? Big deal. It's expired, but the company I work for has built top of the line equipment for 31 years. It's used all over the world, and one system is aboard the Space Station. I personally worked on a number of the modules. You try to insult my age and my education. I pity you. It must be a terrible burden to never be wrong.

Standards do get updated, and if you weren't so closed minded you might be able to learn that.

I'm sorry that I can't help you with your ignorance, or arrogance, Mr. weir, so good bye.

I'm building W1FBs QRP 5 wat amplifier and have finished the board and am testing it but have big problem - I have used a fused 12V battary with a 2.5 amp fuse and a power supply also fused for 2.5 amps and am blowing the fuses (three times) each time I key and never get any power meter response. anybody got a clue. Sometimes you cant see the trees becouse of the woods--- thanks/

Could have been one of the many same circuits that gave me grief
in the past. What I've found from tinkering with SS amps is that
following 'the plan' is very important. A stand alone board may
not work until it is mounted in a box and properly matched and
that type of thing.
No doubt that it is taking off oscillating somewhere in the VHF
unknown and once you get it tamed by rough alignment, it may well
be ok, but equally as likely is that the transistor has already
self-destructed.
Something else that kept hitting me in the head like a hammer when
I was experimenting with these things was that the 99 cent surplus
transistors never behaved as well as the more-expensive name brand
ones.
Its "can't see the forest for the trees". Check the obvious
connections and make sure you haven't made a wiring error, or made
an unsuitable component substitution. Something indiscreet like a
20-50pf trimmer where you used a 10-100pf trimmer can open the
door to erratic operation.
Good luck,

Bill Meacham WX4A

I bought a beautiful old General Radio Signal Generator, and on
learning it was AC / DC cut all the wires, and stripped all that unsafe
crap out.
Now I want to retrofit the old cabinet with modern electronics, can
anyone suggest a suitable module, board, or kit ?

: with the old stuff.

ROFL! Well said. At least when they break, you can fix them
with relative ease. Also, note the prices these items (75A2-75A4)
continue to command when auctioned on eBay.

My dream receiver is the 75A4, but I'll settle for an HRO-60.
Boat anchors both, but they perform their intended function well,
and will still be alive and ticking when the last ICOM and Kenwood
has long since bit the dust! ;-)

Until then, I suppose I'll just have to make my Hallicrafters
SX-71 and B&W 5100 make do for another 30 or 40 years!

Drag out an old ARRL handbook. A pair of tuning capacitors in the
150-300 range and a nice coil/switch or roller inductor is pretty
much all you need.
Alot depends on whether or not you're wanting to match random
wires or simply improving the match of a "close to 50-ohm"
antenna.
Not something you need to pay megabux for.
There's lots of options...once you jump in, you'll further
understand what you can or can't do with a given circuit. When I
first started, I had a penchant for trying to load any old window
screen or piece or wire as an antenna. A simple "L" network
allowed me to play. But if you are using a modern solid-state
rig, the matching requirements are a bit more rigid.
No solid answers here...experiment with what you can rig up and
take care not to blow ur finals or create a bunch of QRM in the
process.

Placing a coupla blocking caps on the in/out connectors, or
floating them, (if they weren't already) would have saved you a
lot of trouble.

: That is economically sound, for any technology that changes rapidly. As you
: mention, infrastructure technology changes less slowly, and should be built
: to last longer, but even that is changing relatively rapidly (on the order
: of decades rather than centuries).

On that point I have to take serious conceptual disagreement. It
is not economically sound when fuctionality requirements are outpaced
by the availability of new technology. New technology is not always
particularly useful, as we are currently seeing in the PC marketplace.

For example, except as toys and novelties, there are no broad-base
requirments for 1,000-MHz computers. In fact, a 200-MHz Pentium
Pro system provides vast overkill for most real computing and
communications requirements. Also, were it not for the gross
designed-in inefficiency of the software currently produced for
common business application, it would be difficult to justify
demand for even a 200-MHz machine.

Don't read me the wrong way, because 800-1,000 MHz systems are
wonderful for playing fast-paced, graphically intensive games,
but other than that only a negligibly small niche market in
science and engineering design requires performance at this
level. Still, for the vast majority of real applications (such
as word processors, spreadsheets, information retrivial, and
general purpose computing), things that would be seriously
impacted were the technology not available, is becomes difficult
to rationalize a need for much beyond 100-MHz system performance.

The same holds true for mass storage. Few people have real working
needs that require more than 1-2 Mbytes of storage (exluding space
taken up by today's heavily bloated application packages).

Getting back to economics, the problem is this. Given an economic
recession that severely impacts consumer spending on recreation and
luxury items, no market exists for the newest generation of
technology (computers). Couple this with a home computer market
that is alread saturated and it follows that this total market

will shrink to the level of replacement demand (not insignificant only because products of this gendre are produced so poorly that their useful service lifetime is limited.

Industry is a similar situation, although for entirely different reasons. That is, industry on the whole has few performance requirements that can justify the purchase of newer technology when the older products are perfectly adequate, except for useful service life and reliability issues. Here again, the market for new computers is limited to replacement units.

Hence, I don't believe it is valid to justify the short useful service life of high-tech computer products as making economic sense based on the rate of technological advancement. Also, I'm not sure that a careful analysis would support the economic sense of purchasing cheaply constructed, short lived products only to replace them with newer products when they fail, except during times of extreme and continuing affluence.

For what it's worth, I'm predicting that during the current economic shake-up, people are going to begin to place more focus on the steak rather than the sizzle that fueled the immediately past 2-3 years of boom times. Industry has already moved in the direction of regarding computers as commodity items, a view that is likely to overtake the entire market. As this tendency advances, the key discriminants between computers is going to become price and quality (equating to useful service life) rather than price and performance (as it has in the past).

The sizzle days were good to a lot of people, and the intensity of the sizzle allowed a great many shoddy products to be successfully marketed, partially the result of naive consumers. Computers were sold on the same footing as "Monster Speaker Cables", with all focus on the sizzle and none on the steak. In many cases, as it turned out, there was no steak!

Today, Intel and a majority of the PC houses have already felt the pinch and have begun belt-tightening. Expect it to continue for some time to come. Some of it, like demand for the Mood Ring and Hula-Hoop, will never return.

When things finally recover and stabilize, I'm predicting that the demand for computers and other high-tech products will have an entirely new slant, 5-year warranties will become the norm (the technology, were it to be properly implemented, can easily support this), and any demand for performance will be gated by actual need.

In other words, the PC marketplace will begin to take on an appearance very similar to that which has always existed in the industrial controller and computer marketplace. You may even begin to see the use of standardized qualification testing of computers, just

as the government already requires of many other products.
Now this would make economic sense and, at the same time, allow
workers in the field to once again make long-term personal
plans or hold a job with the same employer for more than 3-4
years!

Other than the fact that many of the folks who sold sizzle and bought
3-garage McMansions will predictably end up out in the street,
it should be a refreshing change.

Hey, maybe someone will even make a flat-panel monitor with Claw
Feet. That would be cool!

You're talking about products from a time that can't be put far enough in the past fast enough. These products were manufactured by slave labor working 6/14 at poverty level wages. These people worked and lived with dismal and unhealthy conditions. The average lifespan - even in the US- barely broke into the 40's- and this into the early part of the 20th century. This stuff about "elegant engineering" and "earnest craftsmanship" is nearly a psychotic hallucination. I don't call using 10-100 times the material required engineering of any kind. So if we stick a manimal symbol on it- you would consider the 4000 pound cast iron 1/8th HP engine running on crude oil to power your car? I've seen your wretched New England mill towns- and thought I was in hell- these places stand as a monument to wicked manipulation of resource for personal gain- they killed people and nature with reckless abandon. Now take a look at that hysterical excuse of post and ask yourself who the real psycho is here.

BTW- most of that ornamentation that you consider indicative of the designer's pride was pure popular glitz of the time- looks like something created by an opium user with severe lead poisoning. The engineering profession was not held in high regard in those days- the last thing allowed would be individual expression of any kind- so you're wildly off the mark there, boyo.

2124. Kenwood TR-9130

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-05 09:52:36 UTC
From: ON4CLN <on4cln@qsl.net>
Message-ID: <EfXy6.6900$ii5.739989@afrodite.telenet-ops.be>
Source record: 53620

Fellow homebrewers...

Almost two years ago I bought my first rig, a Kenwood TR-9130 2m all mode TRX.
I used it intensely, almost every day for some hours. Although maybe not anymore "of this world", as it was build in 1983 I think, it did a great job. Until...

One day, the rig didn't start up properly, but after a couple of minutes it came through. The symptomes were flickering display, only start-up frequency available (145Mc), no response from dial-knob and the device seemed to reset itself almost every second. Well, those "couple of minutes" soon became half an hour, and in the end it remained in this "resetting mode".

Time to heat the solder iron and take the screwdriver (luckily I had the schematics included). I did some research and apparently, older Kenwod rigs seem to suffer from bad solder joints. So I re-soldered most of the through-platings. This helped, for about one week.
OK, part two: I changed ALL electrolytic capacitors, and re-soldered some extra through-platings, by inserting a thin piece of wire. I did it again!

In the mean time, I located the problem on the digital board, with the display-logic and the microcontroller. When I heat up this PCB with a heatgun, the TRX works just fine. When it cools down... you can guess... The RF and power parts of the rig are 100% ok...

Again one week later, same sh*t! Now I changed some voltage regulators, diodes for transistor-regulators, etc etc. Still no good! The only way to get this rig to work is constantly heating the digital board. I even removed the circuitry that pulls the reset-pin to ground in case of a brown-out (a resistor and a transistor), so there is no more outside connection to the reset-pin. Still: the damn' thing keeps resetting! Is the µC defective? But then why does it work when I heat it up?
I do not want to buy a new VHF rig, as my main interest is HF, but I had so much fun chasing DX on Es last year that I'd like to do it again.

Now, my question is: has anyone had similar problems with this rig? If so, what was the solution? Does anyone need a broken TR-9130 for spare-parts? Does anyone have spare parts from a broken TR-9130?

All input will be greatly appreciated!

Try to find a pair of transmittimg type variable capacitors of
250pF or more. There are lots of published designs. The
best one for your situation will depend on the type of aerial
and feeder that you use. I use a simple T-Match - see my
web page for details (URL below).

I know that this is not exactly the right newsgroup for this kind of post, but I think that it is the most pertinent one. I have a Genrad Model 1657 Digital RLC Bridge up on the selling block, with service manual. 215 dollars shipped, USA only.

Allowing the reset pin (actually any pin) on a microcontroller to float,
completely disconnected, is often a bad thing. It depends on the specific
microcontroller, but there may not be any internal "pull-up" resistors to
ensure the pin goes to a predictable logic level. (or, the pull-up
resistors may pull it to the reset state, not the operating state)

This could possibly be the underlying problem as well; the symptoms you're
describing could well be caused by a floating reset pin. (among many other
possibilities...)

I think I would put that circuitry back, and make absolutely sure all the
connections are good. (even with good solder connections and feed-throughs,
I've seen an apparently good circuit board foil show an open circuit!
Probably a hairline crack at the next component pad.) Use an ohmmeter to
make sure everything actually goes where the schematic says it's supposed
to.

If that doesn't help, I would think about putting a voltmeter on that pin &
making sure it really does go to the level it should. Is there a capacitor
in that circuit? That might be a problem; maybe the CPU *isn't* getting
reset at power-up.

Not even a clue! ;-)

Indeed, the designers/craftsmen of that day had infinitely more creative freedom than do the narrow skill set armies of todays professionals who daily toil in the grand bland environment of their rat maze style working facilities. Indeed, the mental health hazards created by this environment rival the physical health problems created by the worst physical health working environments that existed at the turn of the century. In fact, when you total today's deaths due to stress related conditions including suicides, it rivals those due to direct physical causes at the turn of the century.

Why do you think it is that many of today's professionals are driven to pursue a "more simplified lifestyle" after spending as little as 10-years working within one of today's "ideal" organizations?

Harry, I know New England, and the majority of those mill towns arose to create the textile industry as early as the early 18th century [early 1700's to you]. New England was ideal for this because of all those rivers which were good not only for water power but also for flushing waste products. The "iron age" of the industrial

revolution was supported by the huge iron deposits in the Great Lakes region and the industry built up in that area- namely Michigan. The Erie Canal, which was initiated by another *Clinton*, also known as "Clinton's ditch" at the time, governor of New York, was absolutely essential to making the connection between the iron ore, coal, and product transport. Note that we're not in New England- and actually New England underwent a population drain at about this time due to people moving to the midwest. For your information, Michigan was considered part of the Northwest frontier as late as the latter part of the 19th century. New England never had the scale of industry that was established in the midwest- and this is what you have in mind with your reference to industrial development and the "remarkable benefits of the Industrial Revolution..." in America. .

It has always been claimed that the leading edge of computing is unnecessary for ordinary applications, and it's always been true for a few months. The applications have always expanded to use the speed and memory capacity available. While it is true that with a great effort, much business software could be compressed by a large factor, the cheapening of hardware speed and capacity makes

that uneconomical. As to the need for higher speed graphics and floating point computation, imagine a computer that would produce a screen projection of a three-dimensional antenna radiation pattern in good quality graphics, where you could grab and stretch the antenna wire with the mouse and have the displayed pattern adjust immediately to show the effect of the adjustment? I think that would take more than present-day capability, but it would sure be handy, and I think it will be possible some day.

I believe the max is either 4 or 6 Mhz. I rarely work with our narrow band equipment. I usually work with the new DSP based 70 Mhz equipment with up to 20 Mhz bandwidth, max. The analog models have eight selectable IF's, and some can have an external eight more in an accessory housing, as well as a Spectrum Display Unit to see the whole IF at a glance. I'll check on the 20 Mhz units to give you a better answer tomorrow at the plant.

When I was a student there, the attic of the science building
contained a beautiful set of such demonstrator equipment, some
of it hand created by a professor in the late 1800s. There
was a large glass disc, glass column-with-sphere-and-tube
transmission lines, and hand blown gas discharge tubes with
uranium glass. I regret I no longer remember if the specific
item you are looking for was there.

None of this equipment had been used recently and the College
may well be happy to place it on long term loan.
-Dan Barlow

P.S. I was taught from your book and found (and continue to find)
it an excellent work. Thanks very much!

I am trying to get my ICOM 706 Mk2 G ham radio running
in my new 2001 VW Passat. I am hearing a lot of digi-noise
and S9 birdies every 19.5 KHz through all of the HF
bands. All of the grunge is coming in through the
antenna, not the power leads. I spoke with VW corporate
and they told me to talk to my dealer. The dealer told me to go to Radio
Shack. The dealer said VW is not selling shop manuals for the
2001 Passat, so I don't have much to go on.

Wonder is anyone has tried operating a ham radio in a VW
Passat and knows how to deal with all the noise!

If you can use an MFJ SWR analyzer, it will save a lot of wear-n-tear on your rig, and not make a bunch of QRM, and you will get a good match, quicker.

Well, that's a generic problem. Lots of vehicles generate noise. Best
way to track it down is to start removing fuses from the fuse blocks, one
by one until the noise goes away. Once you have identified a particular
fuse circuit as the cause you can start troubleshooting the devices on that
circuit.

Since the expectation of life is now a whole lot longer than it was
then, this claim seems difficult to justify. The physical hazards of
bad food, unheated housing and work-shops, foul air and dirty
drinking water would seem to be much more lethal than today's mental
health hazards.

> In fact, when you total today's deaths due to

"Deaths due to direct physical causes" presumably does not include
those resulting from direct infection by tuberculosis, cholera or
typhus - a slightly idiosyncratic interpretation of "physical cause".

> Why do you think it is that many of today's professionals are driven
> to pursue a "more simplified lifestyle" after spending as little as

They aren't "driven to pursue a 'more simplified lifestyle'" - they
are paid so much that they can save enough to make this a possible
choice. Your endlessly creative ancestors didn't have this sort of
disposable income, so they could not make this particular choice - it
was "root hog, or starve".

Wow! When did this newsgroup become one of semantics and philosophy? I subscribed to learn about design, help others with design, and simply have something enjoyable to read. All this junk about quality and craftsmanship is just a little troubling. And to think all this started over a professor's request for something not normally found...
Pete

Source record: 53642

New program RXZCALC.exe

PARALLEL & SERIES EQUIVALENT CIRCUITS
==========

For given frequency in MHz this calculating utility will tell you -

L uH which resonates with given C pF and vice-versa.
Reactances of L uH and C pF.

Z magnitude of R and L in series or in parallel.
Z magnitude of R and C in series or in parallel.
Angle of Z

R and L, and R and C, for given Z and angle, either series or
parallel connected.

The basic calculation is as follows - For given values of Rs and
Xs in series, the program calculates the equivalent values of Rp
and Xp in parallel, for a value of Z common to both circuits. Xs
and Xp can be entered either as ohms or in terms of L uH or C pF.
All input and output data is displayed on the screen as an
internally consistent group.

Input and output data is in a form which facilitates step-by-step
network analysis. For example it is easy to calculate the input
impedance of a Pi-L network for a given terminating impedance R+jX
and given L uH, C pF component values. It is necessary for the user
to know what he is doing and not get lost.

Best to begin with sketching a circuit diagram on paper showing
component values. Impedances at various points can then be recorded
to be used later to calculate currents and voltages from input
through to output terminals. Will provide a sound understanding of
how a particular network functions. No more arguments about which
configuration of antenna tuner has least loss.

Download RXZCALC in a few seconds from website below. Only 50
kilobytes. Not zipped up. Run immediately.

If an old Millen neutralizing cap doesn't appear, maybe you could
actually buy a brand-new one: Unadilla, the balun people,
seem to own the Millen tooling and rights, and claim to offer
the products. The Website is http://www.unadilla.com .

A note on the Website says that the owners are ready to retire
and would like to sell the Unadilla and Millen businesses to
somebody who would like to keep them going. So here's
a chance for somebody who loves the old stuff to keep it
alive. Don't know how big the market is for neutralizing caps, or
829B sockets, or all that lovely "Designed for Application" stuff we
used to drool over in the Handbook catalog pages...

I have an applet at http://fermi.la.asu.edu/w9cf/equiv/ that will
calculate the approximate equivalent diameter of a rectangular cross
section conductor. It has links to the theory if you want to do the
calculation yourself. You will have to measure the thickness as well
as the width of the copper strip. You can then either model it with an
antenna modeling code or, if the loop is small, use the inductance
formula for the shape of your loop.

I checked with one of the techs on the IF line, and was told we now have
20 Mhz wide IF's at 20 Mhz center freq, and 40 Mhz wide IF's at 70 Mhz
center freq. That's the -3 Db points, and with a low ripple in the
bandpass.

Dear Tony of London, Ontario.

There are two diameters of consequence - the main loop diameter and the diameter of conductor forming the main loop. Let's not confuse the two.

It does not make sense to adjust the main loop diameter to compensate for any changes in loop conductor diameter.

The larger the diameter of the main magloop the more efficient it will be. Efficiency increases very rapidly with loop diameter. For a loop of given diameter it also increases very rapidly, and at the same rate, with frequency.

Slightly increasing the diameter of the main loop will result in a slightly smaller tuning capacitor setting for the same frequency. Think of the loop as an inductance - a one turn coil.

But changing the diameter only of the loop conductor will have an insignificant effect on tuning capacitance.

The larger the diameter of the main loop conductor the lower the loss resistance. Doubling its diameter halves the power loss for the same current. So a larger diameter loop conductor results in a desirable improvement in radiatiating efficiency with a neglible change in the required tuning capacitance for the same frequency (which is of little consequence anyway).

Varying the overall diameter of the coupling loop only has the same effect as varying the inductance or capacitance in an ordinary antenna tuner. It is just a part of the impedance matching arrangements to a 50-ohm transmitter. The conductor diameter of the coupling loop need be no greater than the inner conductor of the coax cable which feeds it. Just looking at it is enough to convince anybody that the current in the coupling loop is the same as in the inner coaxial wire. The coupling loop can be constructed of a length of wire thick enough to be self-supporting. Only its length or overall diameter is of consequence. Then forget about it !

Download program MAGLOOP4. It will tell you everything electrically you need to know about magloops. It models tuned loops with circumferences up to 1/2-wavelength at which length the tuning capacitor falls to zero pF.

AT RF, THE EQUIVALENT DIAMETER OF A THIN STRIP OF COPPER IS HALF OF ITS WIDTH. Just enter that value in program MAGLOOP4. Download in a few seconds. Not zipped up. Run immediately. User friendly.

The program will show you the modest improvement in signal strength to be gained by using a 4.5 inch wide copper strip in place of a 3/4" copper pipe. The strip is equivalent to a 2" diameter pipe but will be much less mechanically stable than a pipe of that diameter.

Important:- unless the loop is kept well above ground to reduce ground-induced loss, the full benefit of changing from thin tube to wide strip will not be realised. Program MAGLOOP4 will also show you that.

'Tis a fact, a magloop is the most efficient of all antennas when it has to confined to a small space not too near the ground.

But no doubt you will gain more satisfaction by doing your own experiments.

An Elmer who wants his student to learn something would do exactly that.

He seemed focussed on what bands and how much power. Deciding on these is part of the solution but only part. Clearly, he didn't seem to understand what the tuner was going to do, so I was attempting in Socratic fashion to steer him towards the Handbook and the Antenna Book so at least become familiar with what the tuner is doing and to some extent, how.

How do you design a tuner without knowing the range of impedances that you are attempting to transform? As I told him privately, you can hook up some parts and see what it will do, or you can go about it from the other end.

I privately advised him to look at inexpensive low-power tuners to get started and be on the air while learning his way around the technical side.

For the record, a tuner may *appear* to be a simple project, based upon number of components, but how many emails do you read about tuner problems? Hardly simple, Butch . . .

Johnson and Jasik (if I recall correctly) mention an efficient, small loop antenna formed of metal .02 wavelength across into a loop .02 wavelength in diameter. Resonance is achieved by turning the ends of the sheet so they are parallel to each other and act as a capacitor.

I haven't tried it, but it might be an interesting evening project. If I have remembered the dimensions properly, a ten meter loop could fit in a 8 inch cube. That's why I doubt my memory is correct; it sounds far too good to be true!

Do what most people do, and throw a pair of baloney slicers and a big honking roller inductor at the problem?

Really, this stuff isn't rocket science. Unless you have an HP8505A in your shack, you probably don't have any idea of the range of complex impedances your antenna exhibits across the bands. Sure, he could use some coaching in the basics, but the answer to the practical questions he asked are likely to be the same regardless of how the numbers work out.

Hi Clive, if you read the few pages of notes which form part of the
program you will find all the arithmetic formulae used by the
program. They can also be found in any elementary book on AC
circuit theory. The program makes the job of using the formulae
less tedious than a pocket calculator. But you still have to know
what its all about.

So why would you *really* like to wade through the 50 kilobytes of
source code ?

I think most people can make a reasonable judgement based on what the antenna is and what bands are of interest. Sure, you're not going to know exactly, but you can get close enough. Better yet, you can grab a copy of NEC off the net and model the antenna. Again, you need to understand that the antenna will be affected by real world interferences, but you can certainly get close enough to come up with a tuner without resorting to expensive equipment.

Most of us tend to forget that a lot of the basics are within our reach without complex gear. Sure, a fancy piece of equipment makes it easier, but understanding is a lot more satisfying.

2172. Dentron MLA2500 Modification for screen voltage on 4CX400/4CX800

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-08 02:28:55 UTC
From: Douglas Snowden <snowden@peoplepc.com>
Message-ID: <3acfc971@flexnet239.uunt.net>
Source record: 53569

I am still in the process of trying to decide on how to use my newly acquired
MLA2500. I bought it without tubes. I am still looking for the details on the 4CX800 mod that was done in the past. I think it was in QST. I think
I have someone sending me a copy. Anyway, it seems to me that I have the following options:

3CX400A7 (Eimac or Svetlana) both brands expensive.
4CX400 Svetlana - I have a copy of the mod for this.
4CX800 Svetlana - no details yet.

I have not seen any 8875 or 3CX400A7 tubes that were within my budget. The 4CX400 and 4CX800 are. I could leave the amp as is, if I could find 8875's.

But in the meanwhile I have been thinking of ways to come up with screen voltage
for the 4CX mods. I could put a transformer in the box if I could find a place
to put it. I could use a string of several zener diodes off of the plate supply. I could
use the G2DAF (rf rectification method) I have seen a few places. Since I operate
almost exclusively CW, IMD is not too much of a concern within reason of course.
It seems to me that the G2DAF method would possibly be the best way to go, since
the space is so tight in the amplifier.

Any thoughts out there ?

Doug N4IJ

Hey all,
I'm sorry to ask this question, as I saw a post on it a couple of months ago and ended up purging it, but if you had to choose around 20 to 50 general components for amateur radio use, what would they be? I am mostly interested in transistors, but if you can think of other useful items, I would appreciate them also. I appreciate your help, and thanks for your patience!

Best of wishes,
Jeff Barnhouse

Small loops are NEVER as efficient as people postulate because there
are many sources of losses that are ignored, and the radiation
resistance is so low.

Connections are critical, and the capacitor design is critical. So is
conductor loss.

Unless the antenna is jammed up against lossy ground or used on
multile bands, you are often much better off with a short dipole.

The G2DAF ciruit is mostly bunk. It has poor IMD, and doesn't really
greatly increase gain.

A few people report good results (NEVER with actual three tone
testing) while others who do actually test report poor IMD.

Whatever you do for the screen, it needs voltage regulated. The
circuit Svetlana offered had very poor regulation. People at Svetlana,
for some reason, felt differently than the rest of the engineering
world. They felt screen regulation was not important.

The "design" they had for a MLA mod also made the tubes far too easy
to drive.

You NEVER want to run your exciter at anything but very close to the
design output power. Most rigs get more dirty below that level.

> Hey all,
> if you had to choose around 20 to 50 general components for
> amateur radio use, what would they be?

Well, as always, it depends <g>. Do you do mostly VHF, UHF, or HF? Just how comfortable are you with digital logic? What sorts of things do you tend to do?

Let me share what I tend to stock, mostly for HF experimentation.

Obviously, you need a full set of resistors, 1/4 or 1/8 watt work for 99% of situations. I keep a few of all 10% values and when I see a deal on 100 or 200 of common values I'll grab it. radioshack.com has resistors for a penny a piece in 100's, so at least pick up a bunch of 1K, 4.7K, 10K. Amazing how much you use those.

Caps are a bit more expensive, so a complete set isn't really feasible. I get what I can get cheap, but also try to keep a good range of silver micas because they are hard to get when you need them. I keep a big pile of 0.1 and 0.01 monolithics, then try to have a few on hand of a well-distributed set of values. Again, when I see a deal I grab it.

Inductors are a bit more of a problem. I keep a handful of popular values, then a good stock of toroids to make what else I may need. I keep quite a few -2's and -6's in 37 and 50 sizes, as well as quite a pile of FT37-43's for transformers. I keep a small number of FT37-67's, FT37-61's, and T50-7's as well. Speaking of transformers, it doesn't hurt to have a couple of 1000/8 ohm audio output transformers laying around. Again, you can often get deals on these things, so it's good to keep your eyes open.

You gotta have a few SA602 or 612's on hand. A selection of op amps doesn't hurt, either. A few LM380 and/or LM386's are a good thing, too.

Of course, a big pile of 78L05's, along with some 78L12's and a few other voltages. A couple of the 7805's for those LCD's with power hungry backlights is helpful, too.

You always need a big pile of 1N4148's. A bunch of 1N4001's is a good thing, too. A variety of Zeners can come in handy. And of course, you need at least a few MV2115's and MVAM109's. Again, other types as I see a deal.

I try to keep 4-6 16F84's on hand. These things are amazingly versatile but you gotta think different. Also, I keep a few of those teeny crystals (I think it's a C-3 case) in 4, 10 and 20 MHz. I grab any LCD with a Hitachi controller that I can get cheap.

Now to your original question about transistors. I keep a big pile of 2N2222's - these things are as cheap as sand an amazingly versatile. I also have a few 2N3904 and 3906's. A couple of MPF102's, J310's and 2N7000's for the FET end. The PA of any rig seems a bit of a problem. I'm not sure there's a real winner, but the commonly used PA transistors like the 2SC1969 seem hard to get.

Of course, you gotta have a good supply of 74xx parts. Lots of folks like 40xx parts instead. I just never got all that comfortable with them. I guess they are a little more versatile, but the 74xx things seem indestructable <g>

Connections are a major source of loss, and you still can not ignore
what goes on in media around the loop.

Hi,

The list below isn't to bad. I'd add:

2.2 micro farad >20 volt bypass capacitors. Any package tantalums seem to work fine. Use them to bypass the 78L05's and 78L12's.

Electrolytics in the 100 to 200 microfarad range, 35 volt rating - good for small power supply type stuff

LM358 op amps. Cheap and easy to use.

1N4007's (1KV) are as cheap as the 1N4001's (100V)

Any small glass package shottkey (sp?) diode you come accross 1N5179 comes to mind

PIC 16F877's are nice to have ...

2N2369, 2N918, 2N2904 and 2N5108 are all reasonable things to keep around

Pick out any cheap TO-220 NPN and PNP transistors. TIP-xx's are the usual suspects. Good for audio / power stuff.

555 timers are used in a lot of stuff

A spool of number 26 magnet wire and a couple of drill bits will do a pretty good job for low value coils. It's amazing how close you can get. I'd keep a 1/4, 3/8 and 1/2 inch drill bit handy.

Red LED's any size. It's amazing how useful a "power on" light can be ....

Any time anything electronic heads for the trash grab the wall wart transformer off it. They are nice to have to power little projects. If you are into garage sales that's a good source as well.

This could go on forever, I think we're past 50 by now ...

Bob

Dear OM,

I am looking for a diagram of a +/- 500W solid-state lineair amplifier for
HF 80 - 10 meters (+50 Meters if possible).

Where to find a good diagram?

2184. Invitation for "homebrew" magazine

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-08 20:11:02 UTC
From: Jim Stafford <w4qo@amsat.org>
Message-ID: <Mz3A6.1253$NM5.46389@eagle.america.net>
Source record: 53581

Folks,

This is not commercial as we are a non-profit radio club but the QRP Amateur Radio Club International (while promoting low power operation) could be thought of primarily as a homebrew club. Our magazine which is over 60 pages quarterly ($15 per year US) is about 2/3 technical and 1/3 operating. Each issue has several construction articles and is theory packed. We are not trying to compete with QEX or anything but just get more tech oriented stuff out into the community.

If you like building/construction, I think you will like our magazine. Try going to: http://www.qrparci.org for more info. Check out our Quick Links list and also our Technical/Projects page. Subscription info is all over the web site. Also, check out the table of contents for the past 5 years at: http://www.qsl.net/wd8rif/qq_arci.htm

Check us out and get a bigger thrill out of homebrew construction.

Jim, W4QO President- QRPARCI

Motorola have published some nice designs. You should find
some data sheets and application notes on their web site.
I'm not sure about the URL, I think it is: www.mot.com

Try to find the data sheets for the MRF154 and the MRF150.

2189. DIY directional coupler designs

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-09 02:28:22 UTC
From: budgie <budgie@nowhere.cantech.net.au>
Message-ID: <3ad11dab.9186339@news.cantech.net.au>
Source record: 53586

I have been fiddling with a design for a directional coupler usable from say 30MHz up to 1GHz or so, using striplines on FR4. To date, results are only fair.

I have searched the web (without any real success) for details of what surely must be out there somewhere.

Has anyone any pointers?

TIA
Peter VK6ZEG

2190. Anyone have a working 'VT-127' amp out there?

Message-ID: <3gbA6.4572$ix4.3591335@news1.rdc1.sfba.home.com>
Source record: 53589

It isn't just the frequency drift. Various extraneous modes may sweep
through the main mode at certain temperatures and disrupt the oscillator.
These are somewhat analogous to "activity" dips in crystal oscillators.

Peter,

a 400 MHz to 3,6 GHz directional coupler has been published in VHF Communciation issue 2/96. Coupling is 20 dB, directivity is 20 dB up to 2 GHz. It is made of FR4.

Mini Circuits has quite some directional couplers. For instance the 10 to 1000 MHz ADC-10-4 has 10.5 dB coupling and 40 dB directivity (typical, 20 dB min up to 500 MHz). It costs 6.95 $ (quantity 10 - 49).

I know that many folks hate eBay, but that might be a good place to look for your Metrotek CB gear. I see Metrotek sets listed on eBay fairly often. I collect and restore Raytheon, Apelco, and Webster CB gear. the majority of my collection has come from eBay auctions, and I have not had to pay high prices for any of it so far (and I WON'T, if it comes down to that; I don't need the stuff bad enough to over-pay).

73,
Dean, K5DH

Hi Doug,

Good to see you over here on the news group. If I had a copy of the
paperwork on the HV Supply, I could probably come up with a much more
practical way to obtain a screen supply.
Depending on the current layout, one might be able to use a seperate
half or full wave circuit in addition to the onboard equipment.

Otherwise, lots of triodes are out there...

Stay away from the DAF circuits, not worth the trouble they produce while
operating (distortion big time). You want to be concerned with IMD
regardless of your mode.

cheers

First I want to thank for all replies I got from the original question.
Though it appears now as I do not need such a receiver, using the WFM (~150kHz)
filter on the R-8500 works great and produce noise-free pictures from Meteosat 7.

Regards Greg.

NTE has a substitute: http://www.nteinc.com/

Select Semiconductors under the Crossreference drop-down menu. The equivalent is NTE317.
Then select Online Ordering to see where you can buy them.
For example, Mouser Electronics sells them for $60. Good luck.

Gee: What a shame!

A lightweight one to one isolation transformer on the AC input (Sig generators don't take much power) would have ben good idea too! Might just as well have started with a new box and put modern electronics in it! Different technology entirely.

Or is the original poster 'having us on' i.e. pulling our legs? In order to get a recation?

The simplest way I know of is using a fixed value capacitor in
parallel and measuring with a grid-dip meter...which is a pretty
inexpensive item with lots of uses. Also, nowadays you can get
some fairly inexpensive digital multimeters that will read
capacitance and inductance.

Thanks Reg and Kevin. Before I started cutting up $45 CDN in copper strips I definitely wanted to make sure about things. Definately wouldn't want an expensive door stop (although I could pass it off as modern art... well maybe).

As it turns out through modeling, the wider conductor increased my efficiency nicely but the band width was reduced quite a bit. Not that is was all that great to begin with. It'll have to be a design trade off. In the original design the bandwidth was 30kHz on 80m by shaping the drive loop differently (rectangular), so I hope to compensate by trying that with mine.

Once again, thanks to both of you.

Order one of these:

http://www.aade.com/lcmeter.htm

... and build it. It'll measure any passive reactive component in your
junkbox, with more resolution and accuracy than you'll ever need.

==========
You might find US$ 240.- expensive for a piece of (versatile) test equipment
, but with the MFJ-259B analyser you could measure the inductance of all
those inductors at various frequencies quickly and reasonably accurately .

I have no commercial involvement with MFJ ,but this analyser is the most
versatile piece of test equipment (for up to 170 MHz) I ever purchased to
enjoy our common hobby.

2226. Re: Transistor Choices

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-10 18:20:18 UTC
From: Kenneth Scharf <kajfre@telocity.com>
Message-ID: <3AD34EE2.9D8DC428@telocity.com>
Source record: 53523

The CA3028 used to be popular as an IF/RF amp. They seem to be getting scarce thou'. The MC1350 is still around and is a good replacement. 1N4007 diodes actually have a PIN structure and make a good poor-man's PIN switching diode, but 'real' HP pin diodes have lower noise and switch faster. 741 op amps are good for general purpose audio app's such as active filters but are getting a little long in the tooth. Various jfet input op amps are a better choice but slightly more expensive. Power mostfets such as the IRF5xx family make good rf power amps with 12-28 volts supply. Some of these devices will give as much as 100 watts on 6 meters for a pair of them, but circuit board layout and transformer design are critical here. 2N2905 PNP transistors and 2N3053 NPN transistors make good QRP finals to about 15 meters (these transistors can be used as a complemtary pair).

2227. Re: Dentron MLA2500 Modification for screen voltage on 4CX400/4CX800

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-10 18:39:56 UTC
From: Kenneth Scharf <kajfre@telocity.com>
Message-ID: <3AD3537C.4DEA3BD4@telocity.com>
Source record: 53524

There are three ways of using tetrode tubes in the amplifier.

1: connect the grids to ground and raise the cathode above ground and use as a grounded grid triode. This works fine for 'glass' tubes such as the 4-xxx series (4-400 in particular), but the external anode tubes generally don't have enough mass in their grids. The result is that you might overheat the grid structure if you drive the amp too hard. The 4cx800 might get away with this, I don't think that the 4cx400 will since it is built on the same structure as the 4cx250 series tubes.

2: Connect the grids to ground for rf (via capacitiors) and supply normal voltage via low q rf chokes, raise the cathode above ground and drive the cathode. This is the grounded grid tetrode connection. This method takes less drive than grounded grid triode, but more than grid driven mode. You will proably need a resistive pad network to reduce the drive from your rig by 50-75 percent.

3: Connect the grids to normal voltage, the control grid goes to rf ground through a non inductive power resistor. If this resistor is 50 ohms the driving rig will see a 1:1 swr but the amount of power required to drive the linear may be too much if the tubes require too much peak to peak grid voltage to drive them to full output. You can calcuate the lowest resistor value you will want to use from the ohms law and watts law relationships:

E/I*R and W/E*I so W = (E*E)/R etc....

You might have to use a T or Pi network of resistors here to match the power requirements and driving impedance between the rig and linear. Needless to say the resistor network can get kinda large and needs air circulating to keep it cool. Or you could make the resistor network external to the amp and dunk them in a can full of transformer oil like the Heath cantenna.

The handbook has circuits for regulated screen voltage using tubes, TI makes a hi voltage three terminal adjustable regulator that might work.

I knew I didn't have the book, but I checked some others hoping I
might see the same sort of circuit. No luck; I guess my RCA books
are too old for the CA3140.

If you are lucky, the circuit would show up in a data sheet or application
note for either the CA3140 or CA3046. That's not too useful, but
maybe someone is more likely to have those than the specific book,
and perhaps you can find the information on the web. People do
seem to have much success in finding data sheets online, so it
might be worth a check.

This may be hard to find. I had to look up the device, because the
number wasn't one I recognized. The 4029 is a
"presettable binary/decimal up/down counte". It's also supposed
to be a synchronous counter. I don't ever remember seeing it in a
circuit and it's not in two of the data books I checked (including
the only one I have that includes 74HC devices). While it's a
versatile IC, it would be rare that a circuit needed all it's functins,
and there are other ICs that will do the same things, though not
at the same time.

So if it's available, I suspect you'll have to go to place that
deals with industry rather than one that aims towards hobbyists.
Digikey, the only catalog I have handy, lists the CD4029, but I
see no sign of a 74HC4029.

Unless this is to repair something, or a circuit that actually
switches between binary and decimal counting, you might do well
to use a more commonly available counter.

Is it legal to call CQ for a long time :-).

Hearing your own echoes back from the Moon is a form of amateur radar.

If you have so much ERP that you can hear the backscatter from planes,
clouds and heavy rain, the forward scatter would be strong enough for
long distance communication.

>http://www.ibelings.com/n4ip/sskw/
That is a nice unit but what I'd like to see is something along the
lines of a SMPS (similar to those found in the higher power and better
quality car audio amps) powering some high voltage FET's producing a
conservative 1500w pep from a 'stiff' 14v supply.

Class-E PA would do nicely at 90% efficiency. The SMPS would be up near
that efficiency level also!

Any takers.

Let's move onto the next level.

2SC2879's have had their day.

No tetrode was originally designed for GG operation with both grids at the same potential relative to the cathode and anode - if the manufacturers had intended that, they'd have designed a triode instead! The problem is high dissipation in the control grid, but the older glass tetrodes were designed with a high control grid dissipation for class C, so they will survive this mode.

The more modern ceramic tetrodes have a much finer grid structure, closer to the cathode to give high transconductance which allows them to operate at low voltage / high current. This means the grid dissipation is much lower than in glass bottles of similar power output capability, so no modern high-transconductance tetrode is likely to survive the "both grids DC grounded" mode of operation for long.

>The 4cx800 might get away
>with this, I don't think that the 4cx400 will since it is built on the same

BTW, the 4CX400 is quite different internally from the 4CX250. The tube that's simply a 4CX250R with a larger anode is the 8930, which the 4CX400A resembles externally.

The next two methods are the only sensible ways to drive a tetrode, but they do require separate screen and grid bias supplies. There are actually several combinations of DC and RF grounding that will work, and there's an application note on my website which describes each one in turn: www.ifwtech.com/g3sek/boards/tetrode/an-4-1.0.pdf

Unfortunately the voltage rating of those regulators isn't quite high
enough for most tubes (the output voltage rating may be for some tubes,
but the input voltage almost certainly isn't). Again there are
alternative circuits downloadable from my web site.

I think that there is just a problem with the part number. The
CD4029 does exist but I never heard of a 74HC4029. I tried to
look it up in the many data books I have, and on the web, and
came up with nothing. The place that I hunt up most of my parts
is at "http://www.questlink.com". If you can't find it there,
chances are it doesn't exist or isn't made any more.

I think Michael is correct and that what you want is the CD4029.
However, I don't necessarily agree that it would be rare that
a circuit needed all it's functions. Functionally, the CD4029
is very similar to the SN74190, and all it's LS, S, HC, and HCT

derivitives. This IC and its relatives, the SN74191 , SN74192, and SN74193 were used a lot in their days. My experience found the SN74191 and SN74193 more useful than the SN74190 because of the synchronous preload. Because this group of counters was so versatile, we used them by the dozens. The more popular hobby counter, the SN7490, was seldom used at all.

If Paul could give us an idea of the circuit that he is working with, maybe we can be of more help.

Source record: 53532

This comes up over and over again. Apparently, different people have different opinions of what constitutes "expensive". A grid dipper is a nice thing to have, but probably not something you would use all that much. An AADE LC meter is maybe nicer to have, but more expensive. An MFJ analyzer perhaps nicer, and yet more expensive.

You don't need all that stuff, although each makes the job easier. (And besides, I'm pretty cheap!)

What you DO need is an RF probe and a high-impedance voltmeter. I presume anyone asking the question has the meter, but maybe not the probe. So run down to your local rat shack and invest a buck or two, and build one. Chances are pretty good you have what you need in the junk box, so you may not even need to run down to the shack.

Next, you need a low power RF source of known frequency. A QRPp transmitter is fine. Worse comes to worse buy an Epson oscillator from DigiKey for 3 bucks or get real fancy and get a Fireball 40 from NJQRP or a Pixie from HSC for 10 or so. If you like building just make an oscillator from one of those junk crystals lying around.

Now it's pretty obvious, isn't it. Connect the coil in question in series with a known resistor across the RF source. Measure 2 voltage drops and a little Ohm's law and you now know the reactance of the coil at the source frequency. Not too hard to get to inductance from there, is it?

Can't quite get it? OK, suppose you have a 1K ohm resistor and you've built the FB40 for 14.161. (This is a standard choice for that xmitter). For the sake of argument, suppose the voltage across the resistor is 1 volt and you have 2 volts across the coil. XL is then 2K.

Since XL=2 pi F L,
L = XL / (2 PI F)
= 2000 / (6.28 * 14.161) = 45 microhenries

You don't even need to calibrate your probe since it's the ratio you care about. Your meter can even be a piece of junk as long as it's impedance is high. And if you're lazy like me and have a few to do, you put the equation in Excel and just poke in the voltages.

Thanks for the feedback.
I need two for a 9600 G3RUH Modem I'm building for a TNC2 - the circuit lists everything as HCxxxx (ex: HC164 = 74HC164, HC86 = 74HC86 etc) I have everything except the two HC4029. I'll try the CD4029. Hopefully I can get them here locally... I'll let you know how I got on.
Anyway I 'developed' other priorities this morning when my PC's second hard disk died (thank goodness for backups)... spent a frantic day trying to get a minimal system going here hi.

Thanks again!

Isn't there a type of radar (IIRC it is called "bistatic" but I may be wrong on this) where existing high-power VHF/UHF transmitters like TV broadcasting stations are used as the TX "point sources". The user (e.g., amateur) builds an RX system which displayed the reflected echoes from objects as a function of azimuth, elevation, etc.

ISTR a magazine article which described just such a system including a photo of the display. Local landmarks, maybe an aircraft or two, etc. were clearly visible.

Or did I just imagine it ? :-)

Aloha Guys (and Gals)

There's too many newsgroups out there to find the exact one to answer this one particular question, which just happens to be about computers.

So I'm going to rely on my fellow hams, who are also experts in many other fields. Enough stroking? Here's the question:

How can I get rid of the Microsoft Networking logon prompt that pops up every time Windows starts? I know all you have to do is click Cancel, or ESC, to continue loading Windows, but why do I have to keep doing this every single time? Is there a way to get rid of the prompt altogether?

I already did a search on my browser engine and also on the microsoft.com site, but couldn't seem to find the answer.

Thanks for any help and 73s

Why on earth do you want to operate this system from a 14 V supply ?

Are you thinking about mobile operation ?

A normal car alternator is not capable of producing such currents and
the car battery is not very stiff, when 100+ amps are taken out of it.
Feeding 500 W into a HF mobile antenna in a modern car full of
electronics is just asking for trouble.

>Class-E PA would do nicely at 90% efficiency. The SMPS would be up near
>that efficiency level also!

For a home station, why would you first convert the 230 V AC to a
stiff 14 V DC with great expenses and then switch it up to some higher
DC voltage. The Vce(sat) voltage losses alone are 5 .. 10 % of the 14
V switcher operating voltage, so I do not see how the switcher
efficiency could be even close to 90 %.

For home station use, a primary switcher operating from 400 V DC and
controlled by the amplitude information of the audio information would
give a high system efficiency and eliminate the heavy 50 Hz iron
transformer with a light ferrite transformer. A more traditional
approach would be to use a 50 Hz iron transformer and generate a 100 V
DC unregulated supply and use a switcher to drop the required voltages
suitable for the final stage.

Modulating the supply voltage with the audio amplitude should be good
enough for AM, but SSB would require also controlling the RF phase
going into the power amplifier as in various HELAPS designs.

When living close to an airport, listen to amateur frequencies for
repeaters that are just outside normal reach. When a plane is flying
in a favourable direction, quite strong signals with characteristic
"airplane flutter" can be heard from these distant repeater.

Planes can also produce ghosts in local TV reception, especially if
omnidirectional built in antennas are used.

>The user (e.g., amateur)
>builds an RX system which displayed the reflected echoes from objects as a
>function of azimuth, elevation, etc.

It would be possible to have one highly directional antenna pointing
directly to the TV transmitter and an other movable highly directional
antenna to point to the plane and monitor the TV synch pulses on a
dual trace oscilloscope to determine the path length difference
between the direct and reflected (ghost) signals, however, I do not
see how the direction could be automatically determined. While the
az-el direction the movable antenna is pointing to for maximum signal
gives some clues, the beamwidth for any UHF TV antenna is still quite
broad to give exact heading.

==========
Paul , How would you handle the voltage problem for MOBILE operation ?
Would it be sensible to run the high power solid state equipment from a
separate 24 or 48 V battery supply ,charging the batteries from the 12-13.8
V on-board supply via a DC to DC switcher (obviously with proper voltage
regulation and possibly current limitation) ?

If it's Windows 9x and you are not on a network, you 'might' be able to get rid of it. This is an installation choice, and I don't see a quick way to eliminate it. The thing is, you want your computer set up for a single user, not multiple.

In the control panel for passwords, 'User Profiles' tab, be sure 'All users use the same profile...' is selected. Be sure the 2 check boxes on that panel are unselected. Under the control panel for users, be sure there is no more than one user. It wouldn't surprise me if deleting the last user would make the logon panel go away, but I can't be sure of that.

If you are on a network, as a minimum you cannot have 'User level access control' selected, but that may not be enough.

I'm pretty sure you can make it go away with a registry setting, but offhand I can't tell you what that would be. You might rummage through HKEY_LOCAL_MACHINE looking for suspects but be sure to back up the registry first and have a current startup disk in hand.

Here in the US, the FCC has restrictions in place for one-way transmissions by Amateur Radio Licensees. I haven't done an in-depth look at 47 CFR part 97, however I do believe that radar would violate the _spirit_ of the one-way transmission restrictions.

You might want to check into the rules and regs of your own country. Correct me if I'm wrong, U.S. Amateurs, but I'm pretty sure it's unlawful here.

Hi

I've quite frequent had discussions where a 500W amplifier - operated
from 12VDC is requested, only to be used in the shack.......The
appliance operator dictate the technical term for the amplifier he
needs.
Suppose you choose 50VDC for the amplifier, but why on earth use
power regulator at all? You only need 50VDC - a 36V AC transformer
with rectifier bridge and capacitor are all the power supply parts you
need for a linear amplifier (add a fuse and a switch)

one problem is that many VTVM's have insufficient sensitivity when
used with RF probes. They were ufb for valve radio, while for
solidstate experiments even the HP427A isn't good enough, you need to
measure down below 1mV DC.
This is done quite easy using a CA3140E or other op-amp, see
applications notes for simple VTVM for this IC. Diode probes are never
precision measurements, but it is possible to achieve 20% accuracy
over the ranges 30mV-10V 0.1-1000MHz with not much problems using
1N270 voltage doubler RF probe

The only disadvantage to getting it to go away is that the operating system
will no longer remember your logon passwords to other things, like dial-up
networking.

Many switching power supplies use MOSFET devices. For example the IRFP360
is a 400 volt device with a Rds_on of 0.20 ohms. The conduction loss in a
MOSFET is simply Idrain * Rds_on. By paralleling a number of devices the
"effective" Rds_on decreases, thus the conduction losses can be reduced.
Then by using a resonate mode switching design, zero voltage or zero
current, the switching losses can be reduced to almost zero. So with low
conduction losses, and nearly zero switching losses, it is not uncommon to
see well designed switching power supplies with efficiencies at or above 90
percent.

Thus, you can run 5 A and still keep the voltage drop below 1 V.

>By paralleling a number of devices the
>"effective" Rds_on decreases, thus the conduction losses can be reduced.

An amplifier producing 500 W RF would require 600 .. 1000 W of DC
power. Taking this from a 14 V supply requires 43 .. 71 A, thus, you
would have to put 9 .. 14 of those FETs in parallel to keep the
voltage drop below 1 V.

>Then by using a resonate mode switching design, zero voltage or zero

When you start with 300 .. 400 V DC (rectified mains voltage) and 1 ..
5 A currents, obtaining over 90 % efficiency should not be too hard,
however, when starting with 12 .. 14 V and 100 A, obtaining such
efficiency is much harder.

Jim, and whoever else cares:

You may have had several responses to this one off the group, but here's how to do it for those interested (Assuming you are the only user, and that you are not on a network.).

If the Windows Logon is your startup 'thingy' you are in luck. And everything will be simple.
For this case,
1) Go to the Start->Find->Files/Folder and in the search field put the following: *.pwl (star included)
2) Set the search directory as the C:\ drive (or where-ever you have Windows)
3) Hit enter....grind grind grind
4) You should have a list with all logon names followed by .pwl in the box (below the search directory selector)
5) Select them all (Ctrl-A)
6) Hit Delete and watch them go byebye
7) Log out of Windows (may require reboot--but I don't recall if it should)
8) When you get the login prompt from Windows, simply hit Cancel or the Esc. key and you should never see that thing again.

Now, if you are logged into a network, you can do one of two things:
1) Get the TweakUI.exe thing from Microsoft. It has an option on the Network tab that allows you to automagically logon to a network by filling in the check box--but that's not very secure.
2) You can forget about logging onto the network ever again, and get rid of Network Neighborgood. It's easy. It's fun. It's exciting. Left Click on Network Neighborhood and select Properties. Click on Primary Network Logon dropdown box, and select Windows Logon. If you'd like to see Network Neighborhood gone, then you have to find Client for MS Networks (in the 'white' box above). Select it, click remove, and get your Win9x see-dee ready (if you didn't copy it to your hd). Click OK and then you've got to reboot. Next time you reboot, pick up at Step #8 above. Everything should work just peachy.

But do able. It all depends on how much money, and effort, you want to put
in to the design. For example to improve the efficiency of low voltage power
supplies the rectifier diodes are replaced with FETs. The gates are then
driven in sync with the secondary voltage.

Well yes, that is my personal interest, QRO HF mobile operating. No
televisions or VCR's to interfere with!
>A normal car alternator is not capable of producing such currents and
>the car battery is not very stiff, when 100+ amps are taken out of it.
Who said anything about a normal car alternator. For 500w pep the peak
current drain may be rather high but the average current is not.

I run an alternator controller as part of my charging system together
with a couple of split charged deep cycle batteries and can hold the key
down pulling 150A with only .3v drop down from 14.6 off load.

As Leyland said "it can be done" with time, effort and a little
investment.
>Feeding 500 W into a HF mobile antenna in a modern car full of
>electronics is just asking for trouble.
I run two diesels, no electronics, no ignition system and no
interference!

Look at the E-350 alternator (14v @ 385A @ 5000rpm) at
www.electrodyne.com

He also makes a nice 48v @ 100A unit!

Au contrair, Jack. Just lastnight I bottled up 5 gallons of Australian Lager
thats been sitting in a secondary in my basement (55 F) for 2 months. In about
two more months I should have two cases of fine Lager ;-) Yumm.

Friendly suggestion.

This newsgroup is about radios/electronics.

You may not find much serious interest in brewing equipment here
(unless it's on a weekend).

I'm sure that will worth the $95.00 for 344 pages in amazon, but it's
rather expensive!!

There is some in deep theory online about stripline coupling circuit
design?. I searched the net some time ago, and could't find much about edge
coupled striplines.

> Pulse Width Modulator for an AM transmitter.

That is not really that hard to do. There are at least two methods I know about.

The first uses a full or half "H bridge" design. The triggering frequency of the transistors are adjusted to match the resonate frequency. That way the transistors will switch when the current going through them is nearly zero, thus keeping the switching losses low. To modulate the "transmitter" the DC supply voltage must be modulated at an audio rate.

The second method again uses a full or half "H bridge" design. Again the triggering frequency of the transistors are adjusted to match the resonate frequency. But in this case the phase of the transistor gate drive in one diagonal is shifted relative to the other one at an audio rate. The price you pay in this case is switching losses in the transistors, but you feed the "transmitter" a constant DC voltage.

Take your pick.

The first method is what is used in the line of induction heating power supplies the company I work for sells. We currently get up to 90KW out of these units running up to 200KHz. The variable DC power control is just a simple Buck converter. One of the engineers I know, who used to work for a sister company in our group, now works for Harris. He did work on an AM transmitter they are now selling. He told me the design is not that much different from what he was used to in the induction heating power supplies.

I did some circuit simulations using the second method, and breadboarded the logic and drive circuits which seemed to work. I did not build the power circuit, just did the simulations. I did the simulations in Circuit Maker Pro version 6. Keep in mind this was not with the idea of building a radio transmitter. If anyone is interested I can supply a copy of my notes, and the simulation run waveforms. You can look up my E-mail address on www.QRZ.com .

There are some articles, on the web, about class E amplifiers, but this is a completely different animal too.

> be permitted, not being two-way communications?

You don't say which countrys regulations you were interested in
(these do vary, you know :)

In Norway, you can do radar experiments as long as you
observe frequency limits (keep inside the amateur bands),
power limits, modulation scheme limits (a very archaic
regulation we have here) and that you transmit your callsign
every 10 minutes. You will of course need to ensure that
no communication is taking place on the frequency (-ies)
before starting.

I would be surprised if your national regulations mandated
that every form of communication be two-way :)

I was obviously wrong. I looked at the FCC part 97, and it
clearly states that unless specifically allowed, all forms of
one-way communcation is forbidden. I guess other administrations
may have put up similar restrictions.

I don't know if this list has an archive. I am sure this question has
been posted (and answered) before!

I am looking for a company that will generate single pc boards from CAD
file (such as those generated by Electronics Workbench). I seem to
remember a company that would actually provide a CAD program to generate
the files. As would have it, I can't remember the actual company name.

Any help would be appreciated!

I don't hink radar is a one-way communication. If you are using radar you expect to receive the transmitted signal. You will not just be listening to yourself talk, either. The received signal wil be processed to retrieve specific intelligence.

One way transmissions are transmitted with no intention of having them received by anybody. I might be wrong, too, but the one-way thing is not a valid point. There are some other valid points brought out.. qrm , etc.

2277. LM317 mods

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-12 00:37:05 UTC
From: Bob Liesenfeld <wb0poq@visi.com>
Message-ID: <3AD4F8B1.A88EA4F9@visi.com>
Source record: 53473

Hi gang,
I have a power supply that uses an LM317 3 terminal adjustable regulator. It has about +22VDC applied to the input and the usual resistor from the "adj" pin to the "out" pin, and a variable resistor to ground.

As you may know, with this arrangement, the minimum output from the regulator is about +1.2V. So.....I lifted the ground end of the variable resistor, and conneted it instead a 2 resistor voltage divider across a -12VDC supply to provide -1.2VDC to the bottom of the variable resistor in the LM318 ckt. Now the output of the LM318 goes all the way down to 0V. I've checked it under lots of conditions, loaded, no load, cold, hot, etc., and can't find any problems with it.

Before I have a bunch of my students make this change to their power supplies, I thought i'd see if anyone else in this group has tryed this and found any gotcha ya's.
Thanks.

Hi Bob,
The manufacturer's databook info for the LM317 show this to be the proper way to bias the IC down to zero volts. If you figured out how to do this on your own, that's great, but it's a well-known technique! I don't know of any problems doing this.

Well I see several wrong answers.

Go into control panel,
double click networking
about halfway down on the window that opens you will see a pull down list titled "Primary Network Logon"
change that from "Client for Microsoft Networks" to "Windows Logon"
Click OK
From this point on, things can be kind of weird.
Windows will probably ask you to reboot.
When it comes back up, you will have the Windows Logon, not the Network Logon,
the first thing you need to try is a blank password. If that doesn't work, then you need to use the old password to start up windows. Then once windows is started, go into control panel, double click "passwords"
Click "change Windows Password"
Fill in the old password, but leave the new password and the confirm new password blank.
At this point, you should not have to enter in a password again when you restart windows.

Aloha Guys (and Gals)

There's too many newsgroups out there to find the exact one to answer this one particular question, which just happens to be about computers.

So I'm going to rely on my fellow hams, who are also experts in many other fields. Enough stroking? Here's the question:

How can I get rid of the Microsoft Networking logon prompt that pops up every time Windows starts? I know all you have to do is click Cancel, or ESC, to continue loading Windows, but why do I have to keep doing this every single time? Is there a way to get rid of the prompt altogether?

I already did a search on my browser engine and also on the microsoft.com site, but couldn't seem to find the answer.

Thanks for any help and 73s

Check the ads in Circuit Cellar INK http://www.circellar.com lots of PCB vendors there.
Most vendors will require Gerber and Excellon (drill) files. Not sure if EWB produces good gerber output. Autorouters in software that costs less than $2K usually suck. Heck, even the ones that cost more than $2K suck too! Ask anyone who uses ORCAD!

I have used APCircuits in Calgary. http://www.apcircuits.com Their minimum is 2 boards of the same artwork. They have a freeware copy of Protel Easytrax (DOS), which will get you started producing gerbers. They also have a decent Gerber viewer (GCPREVUE) which you really need to use to check your plots before you send them out. They have a quick turnaround and are really decent to work with.

If you're brave, you can go the laser printer (TONER-TRANSFER) route and etch and drill your boards yourself. For single sided boards this is an OK way to go if you have the time and patience.

PCB design and fabrication is NOT a trivial exercise. For the cost and time involved learning the software, and the expense of making a mistake, if you're doing a one-off you'll make out better with dead-bug or vectorboard for RF/Analog, and wire-wrap for digital.

My personal preference for one-offs is single sided clad vectorboard using a pad cutter and point to point wiring. Lots of ground plane and is fairly rugged. Not good for SMT, though...

My colleague and I have constructed fritz Raab's Class-E PA with a pair
of IRF510's. My colleague Peter pointed out to Fritz that some of calc's
were not quite on the ball which he later acknowledged. However, the
design came out with the correct numbers:

700w of cw on 160m for under 10 bucks!

We also matched his 92% efficiency.

Raab and his partner designed a Class-S modulator but have never
published the design.

Back to my point. There has still been very little 'practical' work
published on the web with regards an AM PWM.

Those that run home-brewed pulse width modulated transmitters seem to
keep all their work to themselves and I suppose one cannot blame them.

Regards

Phil G4ZOW

Provided that the Tx/Rx duty cycle is low, only moderate currents
would have to be taken from the 12 V system and thus, there would be
less ohmic losses for a specific number of active devices in the
inverter.

Provided that you have access to the alternator windings before the
rectifiers, you might even try to connect the AC output from the
alternator to a suitable 3 phase transformer and using 3 phase
rectifiers to feed the battery charger. One problem with such
arrangement is that the frequency varies quite a lot, so you have to
select proper transformer core materials.

Nat Semi has a somewhat expensive voltage reference in their application notes.

However, you can use an LM337L -- the TO92 "negative" version of the LM317. This device costs about $0.45 and provides the exact opposite voltage needed to bias the LM317. I have one in a Heath IP27 power supply that I "POOGED" to lab standards.

Ultiboard (made by Electronics Workbench) will provide a variety of Gerber formats. You have to make sure that the format you generate is consistent with that of the board manufacturer.

I have been making my own of late. I recently purchased a HP7475a plotter. (They go for $20 on EBay). The plotter seems to do a better job of printing to mylar than the laser jet. You just create a plot file in Ultiboard (this file can be edited in MSWord -- one of the parameters AA is set by Ultiboard to an "inconveniently" precise level) and send it via DOS command to the printer.

I use the positive boards that Circuit Specialist carries. Very easy to use.

Hi! This is a longshot, but is anyone aware of a Pocket PC (WinCE 3.0) program for controlling an Icom PCR-1000 receiver? That capability is about the only thing precluding me from losing my laptop forever in favor of the E-125. There are several good programs available under Win9X, but I would love to be able to run it from the Casio.

Thanks!

Check out www.4pcb.com they even have online quotes very fast and pretty
reasonable. For Cad software try www.cadsoftusa.com. You can download
a free trial of their software and purchase it for a real reasonable
price for experimenters. I am using it at work under Linux and it is
excellent. 73's Bob N4BK

When Chrysler/Dodge/Plymouth first cam out with the Concord series and V-6
they would wipe out a local repeater (4 miles away) for up to half a block.
I was going to purchase one, but it was impossible to operate on 147.00.
That appeared to be the only frequency they bothered.

The dealer was very helpful and traced the problem to the computer.
The car didn't have to be running, just go open a door. The problem would
continue for a few minutes after you left the car. AS it was the computer
and Chrysler was not interested in fixing it, I bought something else.
Actually there was probably little Chrysler could have done without
redesigning the computer.

I thought of this yesterday when driving along and something swamped the
repeater out. As it uses PL the radio went quiet, but showed a strong
signal. I looked up and sure enough it was one of those older Chrysler
Concords passing me.

I understand that newer ones do not have that problem, but I've not
personally checked
>

> Wonder is anyone has tried operating a ham radio in a VW
> Passat and knows how to deal with all the noise!

Not the Passat, but with all the computers and controllers in cars now days
it can be a real can of worms. Even once you locate the offending device,
it may not be something that can be fixed.

BTW, some car climate controls can be a real bear when it comes to RFI.

I had one of these when they were new and capacitors were a problem then.
I had to replace leaky "ceramic" bypass and coupling caps in the SR-160 as
well as in the HT-44 transmitter and SX-117 receiver. The HT-44 was
particularly bad and required replacing "all" of the ceramics in the driver
stage. When the coupling cap started getting leaky the finals started
acting really strange <:-))

I posted this over on sci.electronics.design, but they're in the middle of a slugfest and I didn't get any response. Hopefully someone over here can help out.

1) I've been working on an LC oscillator, just for kicks, and I've found small amounts of information here and there on them. One of my biggest, and only, questions regarding oscillators is, assuming a pure LC tank, what is an optimal reactance to have per componenet (i.e. Xl = n-ohms and Xc = m-ohms)? I've seen values raning from 180 ohms up to 350 ohms, but no-one really comes out and says "Higher reactance is better..." or "Oh no, higher reactance is not better..." Has there been any work done on this?

2) I'm becoming quite involved in rf design in the 1MHz to 50MHz region, and I'm wondering if anyone's got a list of "core" (no pun intended) powdered iron toroidal mixes and sizes that they could recommend. Since we've now got a good list of active devices recently, I'm curious about the passive devices...

3) One final question: Is there a way to directly calculate the self-inductance of a small wire chunk? I built a dead-bug circuit, but it doesn't function properly, and I'm guessing that there is inductance somewhere that I am not considering.

Any and all help is very much appreciated.
Thanks
Pete

Why not just buy a vhf scanner? Probably less than 100.00 new at Radio Shach,
or an older one for probably less than 50 on EBAY,
Plus you'll have all the other VHF /HUF frequencies as well.

Tom

Amidon will send you a large one-sheet catalog full of formulas and part numbers
for powdered iron and ferrite toroids, rods and beads.

I've got one or two. They also have them packaged with the cores. I was just wondering if there were a few "all purpose" cores. For example, for winding broad-banded transformers (for mixer stages, inter-amplifier stages, etc) is there a 'common' core material used.

Right now I'm using some T25-3 cores, and I'm getting fairly mediocre results at 13.5MHz, but for the time being that's all that I have. I'm making a trip to a 'big city' on Saturday for the holiday and I'm liable to stop by the local full-range junk-box store and get a good variety, but I've got no clue as to what's a "good" variety to have.

I don't think there's a single answer to this question. Tradeoffs are involved, and the optimal choice is likely to depend on the oscillator topology. For a good discussion of oscillators, I recommend "Introduction to Radio Frequency Design" by Wes Hayward. The first edition was published by Prentice-Hall, and the second, now available, is published by the ARRL.

Micrometals is the major manufacturer of powdered iron cores, and their cores are sold by Amidon and other retailers. They used to print a booklet titled "Q Curves For Iron Powder Cores", and it might still be available. Check out their web site http://www.micrometals.com. Over the 3-30 MHz range, at least, I've found type 6 (yellow) to give the highest Q for the typical range of inductances I end up needing for filters, tuned circuits, and the like. You might do a little better with type 2 in the 1-3 MHz range, but if I were to choose a single material, it'd be type 6. The core size you use depends a lot on your power level and size requirements. I use mostly T-37 and T-44 cores, occasionally T-50, for most of my QRP work.

Here's a rule of thumb: 30-40 nH/inch for very thin (e.g., bonding) wire, 10-20 nH/inch for #18 wire.

Thanks Roy. I've got the book you mentioned, as well, however, it's 100miles and 2hours away from me right now. The internet is only marginally helpful if one's got the time to sift through all of the non-pertinent (or too technical) information. I guess it's time to break down and just learn two-port analysis more fully [rather than a cursory understanding].

Core material 6 or 2 would probably work 100% better than the #3 that I'm using.

Again, thanks.

As others have said, most of your tuned circuits for HF beg for a -6 or -2. Unlike some other writers, I tend to prefer the T50's, tho I use a bunch of T37's, too. The 37's are a little small to wind, and sometimes you need a bigger core just to get enough turns without going to a very small wire size.

It's fairly common practice to use T50-7's for VFOs. The -7 has a slightly better temperature coefficient than the -6, making it a little easier to correct for temperature drift (but still a major pain). It's easier to stabilize VFOs at lower frequencies, so you generally need the T50 to get enough turns.

For mixer transformers, etc, the FT37-43 seems the most popular. Occasionally a -67 or -61 will be used for other transformers, but the -43 has a much higher mu so can be used with a lot less turns.

If you are building for a lot of power, you may want a larger size toroid to accommodate a larger wire.

Hi,

The oscillator question is a bit more complex than it looks at first glance.

What you are trying for is the highest loaded Q possible. Since loaded Q includes losses from both the tuned circuit and the amplifying stage you have trade off's. A very typical way to go about it is to design so that half the loss is in the tuned circuit and half the loss is in the amplifier stage.

Since different amplifier stages have different combinations of input and output impedance you have a bunch of variables there. Once you add in the variables from different circuit topologies it can get pretty strange.

On top of all that there are ranges in which a given core material, core size, core shape and winding material will give optimum Q. People in the filter business spend years working out some of the magic combinations they use.

One way to demonstrate what's going on. Take a look at the powdered iron company catalogs. They have nice graphs of Q versus frequency for many cores. Next sit down and wind a core and measure it's Q. Generally you will not hit their numbers. It's not that they are wrong, it just takes a while before your winding technique is as good as theirs.

Not sure all that helps, but there it is.

Yes, type 3 material is a very poor choice for the HF range. According to the Micrometals data, it's best in the region of a few hundred kHz, and isn't good at all above about 1 MHz.

A lot of people see this kind of data for ferrites and reach the same conclusion, but mistakenly. You wouldn't want to use a low frequency ferrite for an inductor at HF any more than you'd want to use a low frequency powdered iron (like type 3). But low frequency ferrites are usually the best choice for broadband transformers and chokes at HF and even above. In those applications, low Q (coupled with relatively high Z) is an asset rather than a liability.

"FT" numbers are ferrites, not powdered iron. This is a very different material, with different characteristics, uses, and tradeoffs. The "FT" system of numbering is used by Amidon, and when the material type is a number, it's usually the Fair-Rite material type number, Fair-Rite being one of Amidon's suppliers. Fair-Rite has a good web site at http://www.fair-rite.com.

As WB8RCR said, type 43 (ferrite) material is a good choice for broadband transformers, although over the HF range, you can get higher impedance per turn squared from 70 series ferrites. Type 43 is better if you're running enough power to the transformer to cause core heating, when the relatively low bulk resistivity of type 70 material is a problem, or if you have enough DC bias to cause a concern about core saturation. 60 series material has considerably lower impedance per turn squared than 43, but would be the material of choice at the upper VHF range. You might also have to use it if even less heating and higher flux density handling ability than type 43 is required. But you also might have a hard time getting a high enough impedance and avoiding self resonance with 60 series material at HF. A few of the 60 series materials look like they might make fairly decent inductors at HF, but most will result in inductors with poorer Q and temperature stability than ones wound on powdered iron cores.

These are the kinds of responses I was looking for. Yes, the differences between the FT and T cores are subtle. I've no experience with anything but powdered iron at the moment. I may pick up some FT-43-xx cores for the transformer, as well as maybe a few more T-3-[25/37]'s for a comparison some time (as broad banded transformers). Since I'll likely be in the 'industry' for some time to come, they won't go to waste.

Bob, do you know where you learned this rule-of-thumb 'constraint' from? This seems intuitively correct [maximum power transfer at equal impedances in parallel], but I like to use the formulas. I'm a glutton for punishment.

> Since different amplifier stages have different combinations of input

I've made that part simple by sticking with the commone-emitter circuit as the basis for most of my oscillator designs. I have been looking closely at the Clapp variation, and have achieved results, but not as expected. My first and final guess was the tank inductor and/or extraneous inductance (i.e. lead lengths).

My main goal, so far, in selecting cores has been to choose a size of wire large enough to produce the desired inductance while nearly completely filling the core surface with wire. The more turns, the better (for my sense of equity), because if I get 10 turns of insulated wire of some sort snuggly wrapped, then I know that the inductance I measure is not going to change much because of physical wire-shape changes.

Your discussion has caused me to rethink some of my original interpretations of what I thought I knew. Even though it didn't directly address the question, it was helpful. Thanks.

Actually it's a derived result for a colpits oscillator in terms of fractional frequency stablilty. Different topologies have different optimum points.

How's your Russian ? The last couple books I saw on this never made it into English .... As I recall they came out by one of the guys at Moscow Power Institute.

For formulas dig out copies of the Frequency Control Symposium Proceedings. They go back to about 194? or so.

Simply calculating how much power is in each part of the oscillator is far from simple. Several authors have made carriers out of it. Most of them have published dozens of papers and a couple of books. Check for anything by Ben Parzen. Key works "osci's" and "lator's" (realy - that's what he calls them). For about $45K (gulp ....) Ben was willing drop by and explain things ...

Check your active stage gain. The oscillator should die at half
current. If it does not then you have to much gain. If you want to do
it the hard way do a spice simulation and check for 6 db excess open
loop gain.

My
> first and final guess was the tank inductor and/or extraneous
inductance
> (i.e. lead lengths).

Once you have decided on a topology take a look at the amplifier(s) as
they go into limiting. Generaly they will have much lower impedances
in that case. This will either drive you to very large capacitors or
to a topology that decouples the resonator from the amplifier. It's
the decoupling process that leads you to more rational components and
circuits that have weird names.

One pretty important part of the process is to measure Q. If you have
a good Q meter then you are in business. If not then generaly you make
a filter and measure it. Then you assume that all the loss is in the
coil (which it never is ...) or you go nuts trying to measure
capacitor Q.

Actually, if you are making oscillators.... I'd want the highest reasonable Q factors as one part of reducing phase noise in the oscillator.

I know this is something of a throwback to earlier technology, but an open air coil has a lot to be said for it in terms of Q and temperature stability.

Granted, it is not self shielded which can be a problem in "miniature" crowded component designs, but for a one-off homebrew system it's likely to give good results.

Well, assuming you are using a good quality mechanical Variable Capacitor.... If you have a varactor diode, and maybe a large tuning range, the high Q inductor isn't going to help much. It's going to be full of phase noise at the best of times and you'd have to lean on a PLL to quiet it down a bit.

In that case, the small size and self shielding characteristics of a toroid would make sense.

What Jim said. In the case where I really want/need to use a core at HF,
I generally use the 'yellow' -6 material, it seems to offer the best overal
Q/permeability combination. I have a stock of T-50-6 and T-68-6 for exactly
this reason.

However, the November 1993 QST, on page 83, has a useful chart of small air-core
coil inductances wound on standard bolts as mandrels which I've made a lot
of use of for VHF/UHF work. Thanks to Dave W7PMD for this.

Can you get your hands on a copy of the January/February 2001 issue of QEX?
There is a very nice article on class-E PAs by Nathan O. Sokal (WA1HQC). He
has a collection of equations curve fitted to data generated by numerically
solving the circuit equations. The curve fitted equations are suitable for
design use. The accuracy appears to be better than 0.5 percent over the
range of data used.

The Fritz Raab design is one of the 43 references he lists at the end of the
article.

> of use of for VHF/UHF work. Thanks to Dave W7PMD for this.

--This is probably worth repeating. Thanks. I'll be looking that one up
when I get back home.

Jim and Dana
I was actually considering the air-wound inductor at first. However, when I couldn't find anything to wind it around here at "home" I sort of gave up. But now that you mention bolts, I may reconsider. I was going to build the oscillator into a Bud box anyway, so it'll be isolated from the final circuitry anyway. I turned to the toroidal cores simply because I happened to have a couple that I got for free at a hamfest, and they were relatively easy to produce with the inductance that I needed.

I have access to an HP LCR meter [one of the fancy ones] at school and have a measured Qu of 85 (averaged over about 3 minutes) [+/- 2.5] for a 100kHz, 100mV signal. That's with leads long enough to stick into the metal fingers on the meter-adaptor and a T50-3 core. I tried fabricating a few air inductors over a screwdriver shaft, but I was getting L in the 0.2 to 0.6nH range (small form, large diameter wire--that's all I had at the time), which is a far cry from the 2.xxuH I needed [for 13.5MHz oscillator]. I was winding the coils with wire that was still in it's plastic insulation, as it provided _exactly_ the spacing required to get the number of turns for the inductance I needed.

And Bob, it's funny you mention Russian, as I've got a co-worker at school who's a Russian major about to graduate (and re-enroll for mechanical engineering).

Anyway, I have much gratitude to this list for the information that has been provided. This summer after classes let out, I fully intend to sit down and

derive some results using fancy math. If I learn anything from it, I'll even post it. Maybe someone else will get something useful out of it.

Again, thanks for the help
Pete

Provided that the Tx/Rx duty cycle is low, only moderate currents
would have to be taken from the 12 V system and thus, there would be
less ohmic losses for a specific number of active devices in the
inverter.

Provided that you have access to the alternator windings before the
rectifiers, you might even try to connect the AC output from the
alternator to a suitable 3 phase transformer and using 3 phase
rectifiers to feed the battery charger. One problem with such
arrangement is that the frequency varies quite a lot, so you have to
select proper transformer core materials.

This website might be of interest.... I noticed a section on
calculating inductors that may be helpful.

http://www.geocities.com/SiliconValley/3569/

Scroll down the left side index bar until you find a section called
DATA/TECH and in that area is the link to the page for calcuating inductors.

I have just got hold of a FT-7B.
In CW, the relay activating circuitry has some very slow action and the first dot almost disappears in speeds around 30 wpm. Is there any ready-made solution for this?
I believe there was something called "Fox Tango modifications" some years back. Is this material avaliable on the net?

thanks

Unfortunately I do not know anyone locally who subscribes to QEX. One
day I'll get around to it.

I'll put out an APB for someone to kindly scan a copy.

I have read something else by Nathan as his name rings a bell.

Equations are not my forte and I leave those to my C.eng IEE colleague
Peter. Give me some metal and I'll make you a fancy looking cabinet.

I would still like to crack the 1500w pep barrier from a 14v rail in the
mobile on 'all-bands'. I'm sure it can be done though the corona and
coil arcing could be a problem on top band.

G3YXM has gone the switching battery route. Not my personal preference
but it works real well for him.

Do a search on his call-sign and it will take you to his page with
pictures, circuits etc. One of the UK's stronger LF mobiles, even on
136KHz!

There may be a problem with using open-air coils (I hope I have followed this thread correctly so far) for a VCO. If the coil is subjected to vibration, it will be microphonic and may modulate the signal if the PLL is not designed to respond to audible frequency variations. The loop reference frequency and loop characteristics will come into play. You may to consider sealing the open air coil in wax or other low-loss RF dilectric material.

If you are planning to "stock up", you might want to check out Dan's
(http://www.fix.net/dans.html/). He frequently has collections of toroids
at attractive prices. Since he only takes orders by snail mail, tho,
sometimes it's a little long waiting. He also has a transformer wire kit
which consists of 3 different colors of magnet wire - a must have for those
trifilars. He does have a minimum order, but he has so much good stuff it's
not much of a problem.

When I'm in a bind, I'll generally order toroids from www.radioshack.com (!)
They have a fair selection, decent prices, no minimum order, and attractive
shipping, plus they will get it here in a few days. Amidon and Palomar
Engineers have a much better selection and slightly better prices, but they
have large minimum orders (and little else I want to fill the minimum
order), expensive shipping, and generally take a couple of weeks.

Also, I would wind a few of those -25's before going out and buying a bunch.
I find them too small to wind easily if there are more than a few windings.

As far as air wound coils, obviously the Q is a big advantage, and I try to
keep some large stiff wire around for the purpose. You can always find
something to use as a form, drill bits, dowels, film cans, etc. But
generally, for frequencies below about 15 meters they tend to get awfully
big. But then, I'm sort of from the Altoids tin school.

It looks like that part is a Logic, Binary/Decade Up/Down Counter, DIP 16 pkg. Seems hard to find.
It's possible that nobody ever made a 74HC... version. The CD4029 (I think #'s like that were Motorola or RCA??) should be OK and, if I've ID'd it right there may be a substitute, MC14029BCP by ON SEMICONDUCTOR, in-stock at Allied Electronics (www.alliedelec.com)

>is the printer port.Any suggestions are appreated

The cable you need will go from the DB9 connector on the laptop to the DB25
on the KPC2.

Most likely what will work is to connect pin 2 on the DB9 to pin 3 on the
DB25; pin 3 on the DB9 to pin 2 on the DB25; and pin 5 on the DB9 to pin 7
on the DB25. Chances are no other connections will be necessary. If you
wire it this way, use software flow control - hardware flow control will not
work.

If it doesn't work that way, let us know & I'll look up the handshaking
leads.

I have a Marconi TF995 Signal Generator that is going in the skip !!!

If some one wants it and is willing to collect it you can have it.

It is old but still works (takes a while to warm up) I.E. you still get
output
from it.
Calibration is well out of date and I give NO guarantee but it is free.
So as I said it is for the skip unless some one wants it

I am in Stockport near Manchester, England.
E-mail me if you want it. mailto:Marconi.TF995@g1gyc.demon.co.uk

Question: Broadcasting stations transmit, whether anyone is listening or not. Is that 'one way'.
Broadcastin an amateur CQ, whether anyone replies or not?
Tranmitting a call on, say, an unmonitored marine VHF channel which does not receive an answer?
CB truckers "Anyone got ears on?".
I think I've missed the point here?
Comment please.

Then it would preclude remote control of models. I think the intent of
that section is to prevent "broadcasting", i.e. one way transmissions, by
Amateurs to a listening audience.

2337. 10 meter repeater

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-14 00:09:26 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <3ad7952c$0$8955@echo-01.iinet.net.au>
Source record: 53433

Dear all
Does anyone have experience in setting up a repeater on 10? I understand that it is necessary to use separate sites for transmitter and receiver as it is difficult to get adequate selectivity with the transmit/receive freqs only 100 KHz apart. (although in percentage terms this is the same as a 2M repeater)
Cavities are obviously physically too big
I would be grateful for info on any working systems.

Richard

I would like to thank those individuals who have given me information, help and lists of materials. Your assistance has been overwhelming, and much appreciated. Hopefully I'll be able to answer my own question in 10 or 20 years, but until then, some of the more technical aspects of what I was curious about will just have to wait. Again, thanks.

The regulator board in my ft101b is kerfut ... I think the
mfc6034a op amp (6 legged dip) has died .. it is configured as
a voltage regulator to supply 6 v to vfo and other things ..
an option is to replace with a more modern device .. but a bit
inelegant on the board .. does anyone know of a source for
a replacement op amp

Thanks
Stephen zl1any

Well, what I said was:

> > > > I was obviously wrong. I looked at the FCC part 97, and it
> > > > clearly states that unless specifically allowed, all forms of
> > > > one-way communcation is forbidden.

"unless specifically allowed" is the *operative* term :)

"Telecommand of model craft" is handled specifically in 97.215,
remote control of amateur radio stations in 97.213, beacons in
97.203. There are no such specifics that allow radars, as far
as I can tell.

There is however something called "auxiliary station" (97.201)
which *is* allowed to transmit one-way communications. There
are some limitations concerning license and frequency bands.
Perhaps this procedure might be used?

--Magne / la1bfa (who should rather stick to interpreting
Norwegian law, which is uncomprehensible enough :)

While I haven't kept track of who, there are companies that deal in
obsolete semiconductors. And even without checking, I'd be pretty
certain this one is obsolete; at came out 25 to 30 years ago, and
then 3-terminal regulators came along. It's not a DIP as we know it
today; all of the leads come out of the package for a distance before
bending, and two of the leads come out further than the rest. This
package setup seemed unique to Motorola.

The MFC6034 is a voltage regulator. A 1974 Motorola Data Book
says it can outpu between 4.6 an 17volts, and can output 200mA maximum.
The input voltage has to be 3 volts higher than the output voltage.

This book is an overview of Motorola products, and does not include
a data sheet for the device or even the pinout. A 1978 Motorola Data
Book I have does not list the device.

However, a 1974 HEP replacement guide has an entry for the MFC6030
(it has a higher maximum output voltage, but otherwise seems the same)
shows the pinouts as:

V.ref 6 1 gnd
bypass 5 2 V.in
V.ref 4 3 V.out

(pins 2 and 5 should have longer leads)

The data book shows other regulators in the series that aren't far
different; how stiff the regulation seems to be the only difference,
and your device isn't even the best of the lot.

The MFC6030 is in the same package, but has can output a higher max output voltage. The MFC6032 also. The MFC6033 seems almost identical to the MFC6034.

Unless the circuit has external circuitry to make the regulator handle more current (which would mean integrating would be a bit harder) I'd just put in a 3-terminal regulator.

i have a small john deere lawn tractor with a failed rectifier-regualtor..
a factory replacement is nearly $100.00..
the device is encapsulated with a a large heatsink and about the size of a
small fist..
it has 3 connections, ac from the alternator and output to the ammeter with
the device being ground..
i got some good 50volt, 35 amp bridges but would like to know what else i'd
need for a simple regulator..
is there any device that i could buy from an auto parts store that would
have the components..
after failure i've been trickle charging the battery but that's not goodfor
the battery..
the current drain is for one cylinder ignition and a pto magnetic clutch..
any ideas appreciated..
tnx
hank

I can't find the original post on this, so I'll tack on here.

Before contemplating radar operation (in the US), you best look at FCC
part 97.305, "Authorized emission types."

Pulse operation is forbidden on most of the amateur bands. This
includes X-band which would be the most logical place to operate a
radar because of equipment availability.

with a little digging i've found the mtce manual..
not very technical but quoting from it follows:
"the stator is single phase, energized by a rotor with 12 permanent
magnets...
no load voltage is supposed to be 28 to 32 volts AC...
regulation is provided by zener diodes that sense the counter-voltage
created by the battery to control or limit the charging rate..
since these devices generate heat during operation, the regualtor is
equipped with finned surfaces to provide greater cooling..
when the battery is low, the reg permits a higher charge rate, and when it
si fully charged the devices limit the charge rate.."
looks like a car regulator won't work...

FSK is not prohibited tho. If you were to use a 3cm Gunnplexer for a low power radar, it would be pretty simple to shift the LO freq between Ft and Ft +/- IF.

By shifting +/- the I.F. I think you would violate 97.307(a):No amateur transmission shall occupy more bandwidth than necessary for the transmission rate and emission type being transmitted, in accordance with good amateur practice.

It's probably easiest to just pick a band where pulse is authorized: 33cm, 13cm, 9cm, 5cm, 1.2cm, 6mm, 4mm, 2.5mm, 2mm, 1mm and above 300 GHz.

This is one of those episodes which drive my enthusiasm for companies like International Rectifier. In this application the Zener is burning the excess energy as heat. A switcher from Unitrode (Texas Instr.) Nat Semi or Maxim can take a widely varying input voltage, varying load and regulate. Just think of all the RFI you could create with the switcher running at 100kHz. The software for the switching part can be found on Nat Semi's website.

I doubt that you would get better gas mileage unless you were building thousands of them.

Most of the commonly avaliable 10GHz stuff is CW doppler
radar (traffic radar). There have been a lot of responses but I
guess no one on here is actually doing it.

Whoops indeed!

RADAR = RAdio Detection And Ranging.

How do you get the range to a stationary (or any) target using doppler "radar"?

Hi Wes...

Radar now has many uses... Identifying weather makeup, discerning the speed of moving objects (baseballs, police radar). I think the current usage of the acronym transcends the original "ranging" aspects dating back 60 or more years.

regards

Pete

Actually, you can do it with a CW radar if you use linear frequency modulation (LFM). The time of arrival of the echo (thus the range) can be determined from the frequency difference between the transmit and received signals. Unfortunately, if there is also doppler from a moving target then it gets more complicated. But it can be done.

Wes

DW is for dual watch. This means the radio can monitor traffic on 2
channels (for example, the channel you and friends are using, and the
general calling channel).

Scanning would do more channels than this.

If you have the brand name, you could look at their website for more
details.

Happy trails,

Hello all,
I have got a meter from an Admiralty portable output meter
PATT A5756 1960 serial N�18 forsale
It is in very good condition for its 40 years of age.
The meter has a paper facia with a 1 volt RMS maker at 50%
scale (I do not know the FSD or current rating of the coil)
The face is approx 3.25 inch (83 mm) dia and is housed in a
flanged black painted carrier, the flange is 4.25 inch (108 mm)
diameter and requires a cut out 3.57 inch (90.5 mm)

```
On the back of the meter is an earthing terminal (for screening
the case) and two terminal that are connected to the movement
one has a "+" marked next to it
The number 46610 is marked below the terminal and this has
been protected with varnish to prevent it coming off.
Also a label with "U.K. Pat. NO. 758363" is attached.
```

Anyone interested ?
I am looking for £5 + P&P but make me an offer !!

```

Message-ID: <3ada46f1.985779125@news.online.no>
Source record: 53363

need an ATU for 21m (69') long inverted-L antenna to be used for 7, 14, 21, 28MHz - it is pretty high impedance at the feedpoint, possibly near 5000 ohms, so I hope to use the same configuration for all those bands. The ATU should be switched for pre-set positions

I am consiering the WARC bands, but already have another antenna for 30m

Suppose a single tuned circuit with tapping for feeder will work for one band, but it is problem to cover 3:1 or 4:1 frequency tuning range using only a single coil and only switching the parallel capacitors

suggestions?

What kind of remote switch? An old remote antenna switch..or
relays? With a relay configuration you could select coil taps
also. Otherwise, I don't think you will get the range you want.

Hello--
I've used a mixture of glacial acetic acid and methylene chloride as a stripper (I don't
recall the proportions, alas). Straight methylene chloride will also work--there's
a paint-removal product called "Zip-Strip" made by Star Bronze Co. of Alliance, OH
that will do the job, but more slowly.

Plan on soaking the assembly for a few days, removing it, scratching away the gooey epoxy,
immersing it again for a few days, until completion.

Note that whatever cuts the epoxy potting resin will also do a bangup job of
dissolving the resin in glass-epoxy PC board, epoxy-painted device markings, etc.

These solvents are unpleasant and somewaht dangerous to work with, so follow the
precautions you'd normally use for flammable/corrosive/tissue-dissolving chemicals.

======================
For remote work (eg outside the shack) I would recommend , a soldering iron
heated by (butane) gas

There are basically 2 types :

1) Catalytic element burner tip bit up to 100 W available in a boardmarker
size unit
I use Portasol which is made in Ireland (Eire) and find 100 W
equivalent more than adequate for any
antenna job. I am sure Weller has a similar unit.

2) Gas bottle with burner and copper soldering bit as available from
Camping Gas (France) or Primus (Sweden) ,the latter running on propane .
These systems involve a larger gas container but can also be used for many
other duties , torch ,paint remover etc. Perhaps not so handy as 1) but
fine for any antenna job.

My experience with high power electric soldering irons is poor ..... the
element often has a relatively short life.

Source record: 53368

For the past while I've been trying to get a buck regulator circuit working using a TL494 IC (a commonly used PWM chip for computer power supplies). I've been having trouble using the error amplifiers and I'm not sure how to bias them. I can use a variable resistor connected to the feed back to control the modulation but this doesn't provide automatic voltage regulation. I need some simple way to get the error amplifiers working.

Anyway I'm beginning to think that EEs aren't as bright as I though they would be, I have heard several times that these chips are easy to use but it's taking me weeks!

Thanks for any help.

Brock

There are many solvents that will attack cured epoxies, dimethylformamide, methylene chloride, diethyl toluamide to name a few. They all take time to work, hours to days, and what is formed is not a solution but a gel which can be scraped off. And how they affect the potted components has to be taken into account. One thing is certain , they are all very hazardous to work with in a home environment. Check the sci.chem news group for more info.

Can you post a complete copy of the circuit as you have it now?. That way
somebody can take a look at it and comment on what is going wrong. It would
be much quicker that trying to describe what you have in words.

2378. Re: 10 meter repeater

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-16 16:00:27 UTC
From: Skipp <skipp@pilot.ucdavis.edu>
Message-ID: <9bf4ur$79s$2@woodrow.ucdavis.edu>
Source record: 53375

Hi Richard,
The quick simple answer is that repeaters of all types are only as good as the receiver front end. One needs to have mucho mucho selectivity and front end over load protection on the receiver or it simply wont play.

When you see old surplus Motorola or GE two-way radios out there with 6/8 front end helical type coils at the receiver input, that's a real world indication the design was well thought out.

Then between the receiver and the antenna, one would also place large bandpass and or bandpass/bandreject cavities in the coaxial line. You must protect the receiver or it just plain won't work.

Now on to the transmitter side...

You don't need 250 watts of transmit power, in fact you will end up hosing yourself up in most cases. Like the receiver, one would hope you have similar bandpass, bandpass/bandreject cavities for the transmitter side coaxial line.

Here's where I'm going with all this... consider your well protected receiver listening to a frequency for some very weak signals. Call a usable received signal 1 or 2 micro volts.

Now think about a transmitter right next to it in frequency blowing 10 watts of power out the door (doesn't seem like much does it..). The difference between the receiver level and the transmit power is converted to a dB value. The math methods of power/signal conversion can be found in any ARRL Handbook.

To have a system that will work well, you have to construct a receiver/antenna/filter system combined with transmitter power output level & all the proper filtering with actual preformance values that add up to a value that "fit within the real world spec calculations."

I made a surplus GE Master Pro Receiver (a very well built unit) into a repeater along with a 2 watt Hamtronics transmitter. Two converted CB ground planes seperated by 60 feet on a wood pole and home made box filters from the ARRL Handbook. Even as silly as it made read, the system playes well from a hill top.

Put an amplifier on the tx side and the noise (remember those dB system values) hoses up the repeater and it all fails with grunge.

So a simple, well made low power system will function quite nicely, same rules apply on six meters.

Add and Scom 7K controller and your set...

hope that helps

You can also add hexafluoro-isopropanol to the candidate list too. BUT...

Basically these solvents swell the cured polymer, making it soft enough
that it can often be mechanically removed. They WILL attack the potted
components.

And Marty is quite correct - these are EXTREMELY HAZARDOUS materials to use
at home. In fact, as early as five years ago, Eastman Chemical Company was
greatly restricting the use of methylene chloride in most labs. You had to
undergo a special training course before you could even get a bottle from
the stock room.

Just today I got on with some construction for the first time in ages, due to health problems, and had a go at a Morse practice oscillator, so I can send Morse with my handheld, I'm learning with the help of another local ham.

The question is about enamelled copper wire, I needed to make some links and didn't have any link wire, so I took a new roll of ECW and tried to remove the enamelling, but it wouldn't come off. The wire in question has copper coloured enamelling, unlike the pink-red stuff I've had previously, which just came off when scraped with a sharp knife.

I also tried burning/melting it with a soldering iron and a candle, these had no effect except that the candle caused surface blackening, which when scraped off left the enamel still there underneath.

Anybody got any ideas?

73's, Alex M1HAR

2386. Johnson roller inductor question

Try soaking it in Acetone, in a covered container, for several days.
This MAY do something.

Sounds like you have some high-quality polythermalized magnet wire
there. You can't strip it with heat, at least not with anything short
of a welding torch.

What are you trying to use the wire for (what is a "link"?)

As John Miles, KE5FX, noted, the wire is probably covered with Polythermaleze (Belden) or another similar coating. These coatings are extremely tough and difficult to remove. If you can still find it, GC Electronics sells a material called Strip-X. You heat the wire slightly and dip it in this material. Let it set for about 20 seconds and wipe the insulation off with a clean cloth. Unfortunately I have not seen Strip-X sold for quite a while. It was originally made from a mixture of phenol and potassium hydroxide. A later version used either phenol or cresol and methylene chloride. Both versions are extremely dangerous, especially the later version. This stuff will eat through latex gloves in seconds and then right through your skin. [There have been deaths recorded from spilling a very similar mixture on the skin, coating an area no larger than the size of a silver dollar.]

A better approach is to heat the wire to redness until the coating burns or carbonizes. This will mean a better heat source than the candle. Once cool, the wire end should be cleaned with fine sandpaper to remove the oxidation.

Thank you for the reply. DW is indeed dual monitoring of 2 channels. This is a marine set and there is a "default" channel 16 (much like ch 9 on CB) and DW switches between 16 and another selected channel at the rate of about 1 switch each 2 seconds. Unfortunately this brand (Venus) is an obscure Japanese set, and I doubt if any website exixts.

Those of us in the US would say a "link" is a "jumper" wire
The Brits sometimes also use the term "shunt" where we might use
"jumper"

If you're going to have to use sandpaper anyhow, wouldn't that remove it
without the other steps?

->Sounds like you have some high-quality polythermalized magnet wire
->there. You can't strip it with heat, at least not with anything short
->of a welding torch.

Oops, sorry, John. Polythermaleze (Belden trademark) is INTENDED to be stripped with a soldering iron, or even better, a solder pot. That's what the "thermal-ease" at the end of the trademark means.

My suspicion is that he has formvar or some other good tough coating that will strip, when done properly, with a hobby knife (X-acto or similar), or as noted, with sandpaper.

Me? I spend the $5 and get a small spool of polythermaleze.

Bob,

I don't have the catalogs here at the ofice, but the electrical perameters are varied for each model. The inductance and maximum circulating current allowed are key - 5uH/3A, 10uH/5A, and 18uH/9A as I recall. May be off one model, as they offered a 28uH unit in the lineup.

Absolutely they are NOT all 10uH. If you need specific's email me and I'll review old catalog.

I will just answer the question.
By links do you mean small jumpers on a pc board.
You really don't need insulated wire for that.
If you DO need insulated then WIRE WRAP is pretty good.
On pc board I use "zero ohm resistors"
Sold on a band like resistors but are shorts. Bend nice and look good.
Other than that just hook-up wire is ok.
Not sue if I got . or , in correct places.
As long as my links work , they don't know.
Johnny G3LIV.

Jim Weir was correct, the wire coating is Formvar - not Polythermaleze.
Formvar(R) is an extremely tough coating. Sandpaper will have great
difficulty in removing it.

After burning off the insulation, the sandpaper removes the oxide coating
which is a trivial operation. In fact, I generally use a Scothbrite
kitchen scouring pad rather than sandpaper. Simply pulling the wire
through it while the pad is squeezed with the fingers is al that is
necessary. You will not remove Formvar this easily!

You can also dunk the still red wire into methanol which will reduce the
oxide to copper.
[And if you have a calibrated nose, you can smell the formic acid produced
by the oxidation of the methanol.] I did not suggest this initially as you
generally have an open flame to heat the wire and an open container of
methanol nearby is an accident waiting to happen. The scouring pad is a
much safer option and the one I suggest.

Dr. Barry L. Ornitz WA4VZQ ornitzNO@SPAMusa.net

Remove the NO SPAM to reply.

Formvar is an epoxy modified polyvinyl formal resin. It has an
exceptionally high peel strength which is why it is so hard to remove from
the wire.

Hmm. That's interesting -- I could've sworn the 10-pound spool of #22
magnet wire I wound my Tesla coil with was sold as "polythermalized
magnet wire." The idea was that arcs drawn off the secondary
(intentionally or otherwise) wouldn't burn off the enamel.

It was nice stuff, I still have some. You can't strip it at soldering
temperatures -- no way, no how. Only mechanical abrasion, from
sandpaper or a knife, would do the trick. I'll have to look back at
some of my old references to see exactly what they called it.

Either way, why use enamelled copper wire for normal electronic wiring?

Try FAR Circuits. He does many of the QST boards. Look for any
articles using a PCB and FAR usually is advertised at the end. Fred
does that sort of thing.

Ditto.

The only 'problem' with a linear series pass cranked down to a low
voltage is the extra series pass dissipation. Don't think an exrea 1.2
volts'll kill ya.

Thermal strip enameled wire was commonly used at a company I worked for, and I've used it for many years for prototyping and homebrew projects. There are at least a couple of varieties of it (and probably several different manufacturers), which differ in ease of stripping. In a production environment, it was stripped by dipping the end into a pot of molten solder. It's not easy to strip with a soldering iron, and at least one variety is pretty difficult. The first problem is getting good thermal contact with the wire, which requires scraping pretty hard with a well-tinned iron, or getting good contact to the wire end. The second is getting it hot enough. I've found that about 800 F is needed for stripping in a reasonable length of time. You can strip at the more common tip temperature of 700 F but it takes longer. At lower temperatures, you might not be able to get it off at all. Finally, you've got to be patient. The stuff boils away, which takes a little while. The larger the wire, the longer it takes, since larger wire is cooler closer to the work area. The largest I've routinely dealt with is about #22 -- larger wire would take more patience yet and/or a big iron. The residue is easily removed by rubbing with the iron or with light sanding.

I have no idea whether some of the wire being discussed is thermal strip or not. I'm just pointing out that it would be easy to not recognize thermal strip wire if you did have some.

2410. Re: 10 meter repeater

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-17 22:31:28 UTC
From: Steve Noskowicz <sorry@junk.email.returned.com>
Message-ID: <3ADCC440.897866E5@junk.email.returned.com>
Source record: 53307

Richard,

There are two main considerations for duplex operation. Receiver filtering and transmitter filtering.

A filter on the receiver reduces (attenuates) the Tx power to a level acceptable to the receiver. The specific level depends on the receiver design. The effect is generally two pronged. The Tx power can overload the front end directly OR the Tx carrier frequency can mix with noise coming from the LO (which is one IF away from the LO freq) and create noise on the Rx frequency. (See sideband noise below)
This filter must attenuate the Tx frequency.

The other aspect of the 'duplex' problem is that a transmitter has noise extending out from the carrier. We call it sideband noise. The amount depends on the transmitter design. In general, a crystal controlled transmitter will have lower sideband noise than a synthesized one.
The filter on the transmitter reduces this to a level below the receiver sensitivity. This filter must attenuate the Rx frequency.

Using two antennas provides some of both of these types of attenuation. Vertical displacement of vertical antennas yields better isolation since there is less radiation up/down.

Good luck

I just picked up a used Yaesu FT-890. When I went to try out AM while listening on another receiver it sounded like it was on sideband. Looking at the wattmeter, there wasn't a carrier I flipped the other receiver to upper sideband then lower sideband hearing the signal just fine on either mode. Being a new comer, I think this is referred to as double sideband mode?

If so, is this normal? Or is this some kind of modification an owner would / could have made? Or is the radio just plain broke? If it is a modification, why would somebody want double sideband (assuming I'm right) on a HF radio?.

Any thoughts???

Scott.

The radio is in need of adjustment. Double sideband is not a
featured mode of the Yaesu FT-890.

Before I shipped it off, I would check with a station some
distance away.

2415. Load Z for given Zo, dB and measured Input Z

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-18 03:43:16 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9bj2c2$k1o$1@plutonium.btinternet.com>
Source record: 53312

NOW AVAILABLE.

Updated version of PROGRAM "ZL-ZIN.exe"

Coaxial and Balanced-pair Transmission Line Calculations.

This program computes the value of the load or terminating
impedance which
must exist at the end of a transmission line of given Zo and
attenuation for
a measured line input impedance. It is tailored specially to
calculate the
feedpoint impedance of an inaccessible radio antenna from input
impedance
measurements at the readily-available transmitter end of the
feedline.

Another application is the precise design of transmission line
impedance
matching transformers.

It can also be used to correct errors perhaps due to unavoidably
long test
leads when measuring radio components at HF.

As the transmission line becomes longer it is necessary to know its
characteristics more accurately. Simple means of estimating line
characteristics are described in the notes.

This is an updated version of a program of the same name issued in
1999.
There are some minor changes in the accompanying operating notes
and a
facility to sweep measured input reactance in small increments from
the
keyboard has been added. Mathematical operations and computed
results
remain unchanged.

It is suggested you download this new version and if you already
have the
earlier issue overwrite it with this one dated 15th April 2001.

Download ZL_ZIN in a few seconds. Only 52 Kbytes. Not zipped up.
Run immediately.

"Did you really think we want those laws observed? said Dr. Ferris.
We WANT them to be broken. You'd better get it straight that it's
not a bunch of boy scouts you're up against.... We're after power
and we mean it .... There's no way to rule innocent men. The only
power any government has is the power to crack down on criminals.
Well, when there aren't enough criminals one MAKES them. One
declares so many things to be a crime that it becomes impossible
for men to live without breaking laws. Who wants a nation of law
abiding citizens? What's there in that for anyone? But just pass
the kind of laws that can neither be observed nor enforced or
objectively interpreted--and you create a nation of law-breakers--
and then you cash in on guilt. Now that's the system Mr. Reardon,
that's the game, and once you understand it, you'll be much easier
to deal with." --Ayn Randrad

I'm trying to determine the time jitter is a square wave due to phase noise on the oscillator. I understand that the jitter, or allan varience, is the integral of the power spectral density. But how dpo ypu go from SingleSideBand Phase noise to Power Spectral density? I've seen a spreadsheet at Wenzel Assocs that multiplies the SSB by 2. Then I've seen from HP that SSB= (f^2) * PowrDensitySpectrum. I'm confused. Any help?

Source record: 53319

Script L(f)., commonly known at SSB phase noise, plus 3 dB, equals S sub phi of f, commonly known as power spectral density of phase*. I don't know what HP app note you are referring to, but as you say, you are confused, and the app note is talking about something else. There are many definitions of jitter, but you are correct in that they are basically integrals of phase noise. The Allan variance, OTOH, is *not* a simple integral of phase noise. Rather, it is equivalent to a convolution of a particular function (kind of looks like a sinc function) with phase niose. There is no simple relationship between the two. For further details, read Michael Fischer's papers from the 1976, 77, and 78 Frequency Control Symposium (available through IEEE UFFC socieity).

The difference between jitter and Allan variance is as follows. Jitter attempts to find the variance of the frequency error. However, the variance, as defined by classical statistical theory, is infinite. Thus, a high pass filter function is imposed to make it finite. The Allan variance (which Allan calls the two-sample variance), uses a first difference technique to implement what is in essence a high pass function, but the function is not a simple one when descrbed in the frequency domain.

Rick Karlquist N6RK

*approximately, for values less than about -20 dBc.

Hi there,

Although double sideband wasn't supplied as a normal function of your radio, there are simple mods which allow it.

I installed the same mod on my TS-430 to allow double sideband, of which I use on 40 meters. Conversations within the West Coast "War Zone" are often jammed. We use double sideband when the bandwidth allows to ensure a valid signal can be heard in most cases. Listening is done on which ever sideband is the most clear at the time.

So, check your radio out to see if there is in fact, a mod in place to enable double sideband. Searching through the common and available modification web sites might turn up the actual mod.

cheers

What? Using twice the necessary bandwidth just to communicate? Why not
just move 3 KHz to a clear spot? Sounds like you would be adding to
the "jamming" or just irritating the other guys causing them to jam you
in retaliation. Sounds like 75M at night. Please don't spread these
ideas to the midwest where we co-exist in peace on 40M.

Yes, but will microprocessor crystals work for transmitting (QRP) in a radio? I thought there was something about capacitance and tolertant,
etc...? If so, that would be great! Either way, thank you for the reply and I look forward to learning more about this.

Scott,
You need to dial in a little carrier. The CW carrier controls
that.

Yes of course.

Now it may be, that in your circuit, a 28.322 MHz crystal will oscillate at 28.319 or something, but who cares, as long as they all oscillate at 28.319. And in most circuits, you are going to use a trimmer that lets you adjust the crystal over a wider range than the load capacitance difference anyway.

Crystal load capacitances don't vary over all that wide a range anyway, and you will mostly use 10% caps, so your circuit will vary.

One approach I used experimentally is to use these little Epson oscillators. They are about 3 bucks and you can order them for whatever frequency you want. There is some phase noise so you wouldn't use them in a high performance receiver, but for some local 10 meter playing around they are just fine. You can't move them at all, however, so if you are going to use them in both a transmitter and a DC receiver, it can be a little tricky.

If you are only interested in transmitting, NJQRP has a transmitter kit that uses a microprocessor oscillator at 28.322 and has a division circuit so you can use it on 80, 40, or 20 as well as 10. The kit is $10 I think. I have used the Epson oscillators in that circuit as well and they work just fine.

Darn, there goes the neighborhood! ;) I guess I just don't see the
wisdom of modifying the transmitter and transmitting DSB, supressed
carrier when a flip of the switch can put the rig into AM mode and keep
the carrier, for 2 interfering signals instead of just one.

Just when I was getting used to that "new" math stuff ;)

How's this sound:
If I convert a sine wave to a square wave, the phase noise would cause
a jitter in the square wave. To figure how much, everything I've read
indicates that the jitter = the integral of the (SSB + 3 db)
divided by 2PiFc. Using this method with SSB numbers from HP catalog
gives jitters about 5 pSec.
Does method seem cirrect?

Nope, rotating the carrier control to any position doesn't produce any carrier. Only when I speak into the mic does it put out power (swings up to a full 100 watts just like SSB mode does). The received audio (AM) sounds just like a SSB signal.

Not to mention the effect of the mixing of the audio with the carrier and having all sorts of products. Well the quality of the QRMer has certainly gone downhill since Riley showed up. HI.

If you all want to know how to really trash up a good radio check with K4OKA and KA8WAM, they win handsdown.

You're prolly right. shunt = jumper may be a figment of my imagination.

I've been amused by English/American crossreferences (like in the Haynes manual for my old Volkwagen KG) where they get some of the terms totally wrong. He's an exerpt from a Control Techniques VFAC drive manual (made in Wales):

English American

Amoured Conduited (WRONG! Americans say "Amoured" also)
Commissioning Startup (Americans use both)
Cubicle Enclosure
DC Link DC Bus
Earth Ground
Enable Allow (WRONG! Americans say "Enable")
Encoder Pulse Tach (?)
Energise Turn-on (I would normally say "Energize")
Fit Install
Fixing Mounting
Healthy Normal
Link Jumper
Screen(ing) Shield(ing)
Mains Power system
Mounting Pillar Stand-off

-RAT

That's a spectrum analyzer, not a scope. You should be able to snag a manual from one of the sources listed at http://www.reprise.com/host/tektronix/home/default.asp -- hit the "Resources" link at the top of the page.

No real American would ever spell it "Armoured", never mind your typo above.

Some time ago, 73 magazine published a schematic for the "Simplest Transverter". This circuit converted a 2 meter input to a very low power 6 meter output. I am looking for this diagram and am having no luck on the 'net. Anybody have a copy or can point me in the right direction ? Any help is greatly appreciated. Thanks in advance !

My 1977 TRW data book goes only to PT9797. They sold the product
line and the fab to Motorola shortly after this, but your PT9839
isn´t in my Moto RF device data book, either.

Thanks for the reply
I appreciate the problems with front ends and transmitter broadband noise
etc
However cavities are not practical on 10M due to size.
Can you get away with stub or other filters and isolators?
I am looking details of a setup which works without having to locate the
receiver at another site.

The signals you are referring to are Vertical INTERVAL Test signals, that may be inserted into undisplayed lines of the television signal. These lines are used for such things as Closed Captioning, TV station ID, Ghost Cancellation and of course, Test Signals. The equipment used is commonly called a 'VITS Inserter', or Vertical Interval Test Signal Inserter. For the broadcaster, a 'Pre-distorter' is used to litterally distort the video signal in a very selective way before it goes into the TV exciter. While monitoring the VITS of the received and demodulated signal, the pre-distorter may be adjusted to compensate for nonlinearities of the transmitter and undesired effects of the transmission line and antenna. Thus, the received TV signal is a very close, distortion-free replica of the signal applied to the TV transmitter.

Ed
I would look at the manual to see where the carrier control is. I think in that rig there is a control either on the rear of the rig or on the inside to controll the carrier. Most Yaesu rigs sound pretty good on AM.

73 and good luck
Oris

Look Scott and you other goofs...

Since you all blew writen hot air out in a followup before you thought it through, I'm only going to review the facts one time.

Go back and read my follow up post where I explained how DSB is used as an effective means to thwart jamming. Moving solves nothing as jammers will often follow. It's a practical solution that works well and costs little.

Your irritation comment is way out of line and shows you don't understand or have much experience in the real East/West Coast 40 meter experience. A day band by nature, 40 meters doesn't cover out of the regional State(s) of your "compared to - less populated area." So forget trying to make any type of informed comment when you don't have the information or experience of what happens in our areas. You never addressed the original authors information request, just blew a lot of trash onto the news group here.

I seriously doubt you or your other blow-hard friends would be able to provide the original Author any useful topic information.

Using Double sideband in legal bands makes much sense over AM, a trip through any Communications or Radio Handbook will explain why. An ARRL Handbook would be a great place for you to review the basics.

So go find some other post to comment upon where you have a better understanding of what's actually going on, both hardware wise and out in the real world where it's applied.

Hello,

I have some EL 37 valves in stock. They are all NOS and obviously made
by Mullard. Some of them are branded Haltron and some Mullard, but
they are identical so I am pretty sure that the Haltron are just
rebranded Mullards. After all, Haltron never made valves, just
rebranded and distributed.
US$ 113.- each or best offer. I can send a picture.
E-mail me if interested

From: "Clifton T. Sharp Jr." <clifto@clifto.com>
Message-ID: <3AE0943D.495B344C@clifto.com>
Source record: 53254

I'm interfacing to the output of an R/C receiver. The control outputs are variable-width pulses, varying between something like 1.2 and 2 ms. I want to change that to a proportionate voltage level (say, 0-1V). Simplest idea I can come up with is charging a capacitor with a constant-current source and using a sample-and-hold to steady the output, and of course scaling to the desired range with an op amp. But that seems like so much hardware, and my gut is telling me there has to be a simpler way. Ideas?

I don't think it's going to be easy. You're looking at a phase shift of +/- 120 degrees, which could possibly be done by using some sort of reactive network, however would, IMHO, be lossy (I'm not up on AC theory that well, but I know the basics, so feel free to correct me).

Most likely, and this would be lossy as well, I would suggest using a three-phase generator, possibly powered using a motor run off the mains. You wouldn't need to worry about power-handling capacity of reactive elements, and you would have simple, direct 415v3ph power off the generator.

Another option would be to see if your local power company can provide you with a 415v (480v?) 3ph power drop. It would be expensive, but if you're running big guns, may be your best bet.

If you don't mind my asking, why do you need that paticular level?

Hope it helps,

Henry C. Gernhardt, III

Skipp,
First off, give me your call sign so I can see how long YOU'VE been
licensed. You can tell me until you're blue in the face that using DSB
"to ensure
a valid signal can be heard in most cases" is the right thing to do.
So, are you listening to one of the sidebands or both in the RECEIVE
mode? It sounds as if you listen to one of the sidebands, whichever is
interferred with the least. If so, you are sending out at least twice
the bandwidth as what you are listening to. That doesn't seem to be
"good amateur practice." In the midwest, this would almost be called
malicious interferance on your part. I don't see how you conclude that
"DSB is used as an
> effective means to thwart jamming. Moving solves nothing as jammers
> will often follow. " What if the jammer just moves his signal up or down a couple KHz and
starts interferring with the sideband you're listening to?

In Europe we get these inexpensive clocks that automatically update from a transmitter somewhere in Germany every hour or so. Does anyone know the frequency and the specifications for these signals?

simplest idea to me would be to hook a cheap servo to a pot with a DC voltage
on the pot. Could be scaled with a couple of resistors.

Scott,

As you, and many others, have already surmised Skipp is a raving idiot.

Anyone that advocates using DSB to avoid jammers is a jerk.

All going to DSB proves is that he could care less about interfering with others, as long as he gets through.

Thanks Dan,
That was all I was suggesting in my first reply to his original post. I assumed he was fairly new and didn't realize what he was, in fact, doing. Moving up or down the band is the best approach...at least others won't consider you a lid by being polite and giving up the frequency in search of a clear spot. Chances are that someone else may have had a QSO in progress when the band conditions changed and made the other station audible to the other. Many times I get amazed while listening to a QSO in progress when all of a sudden I hear a new QSO on frequency, obviously not just starting out and one group will jump on the other that the frequency is in use although the other QSO was probably in progress as well at the same time, then the skip distance changed and "voila" interference.

"Why can't we all just get along?"

2469. Measuring S parameters

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-21 01:35:58 UTC
From: Bob Liesenfeld <wb0poq@visi.com>
Message-ID: <3AE0E3FE.3D60B385@visi.com>
Source record: 53266

Hi gang,
Before I knock myself out trying this, I thought I'd get the group's thoughts. I'm thinking of building a basic network analyzer to measure reflection coefficients and phase angles (aka S parameters) of some BJTs (2N2222, 2N3904) at HF.

I have several mini-circuits directional couplers rated for HF and a 60MHz dual trace scope. My plan is to build a compact (low stray L and C) test jig for a BJT, with adjustable bias, make up some 50 Ohm terminators, and a stable xtal oscillator with a choice of 3 or 4 frequencies around say 10MHz and 50 Ohm Zout.

By connecting the directional couplers between the oscillator / test jig / termination, I think I can come up with S11, and S22 (at least the reflection coefficient part). I would use the scope to read incident voltages and reflected voltages (with a compensated X10 probe).

To get the phase angle part of S11 and S22, I am thinking I can use the dual trace capability of the scope to measure the phase angle difference between the incident and reflected waves to perhaps a couple of degrees.

My goal would be to get some reasonably accurate values for S11 and S22 (and maybe S21), at a few HF data points to then plug into a smith chart or the ARRL Radio Designer BIP model. Manufacturers seem to have *some* S data for VHF and up for a few devices, but not much for HF. I would not be attempting these measurements above say 20MHz.

So....Am I *dreaming* or does this sound like a do-able project?

Thanks for any ideas!

I'm not so sure that is a good mod to make Bill. The screen regulation
will be poor, and it overloads the transformer winding.

It also drives too easy.

As I recall there were some backwards electrolytic capacitors in the
schematic of the voltage multiplier system.

AFAIK (as an EE with 35+ years under my belt - and my wife says they
show), there are only three ways to do this:
1. Static converter
This is similar to a UPS, with a rectifier/battery/3-phase_inverter
string. Not the sort of thing you would build yourself, but you could
get the individual pieces and you could practically configure it.
2. Rotary converter
A single phase motor coupled to a 3-phase alternator.
HEAVY. Losses at both ends, and losses at idle are more than a sane
paying customer would tolerate.
3. Modified Scott transformation.
Originally configured for a single 90 deg shift to obtain two phases
in quadrature, you can play with this to get other shifts
artificially. Would need a bank of transformers.
HEAVIER and lossy.

None is really a pretty solution, the static being the best bet and
the lightest.

>With the result being not to heavy.

Not all that likely, see above.

It would probably be preferable to open the servo and tap onto the pot
inside it.

Do you need a clean 3 phase feed or do you just need a rotating magnetic field for a phase electric motor. In the latter case you might try a trick that i have seen some decades ago in a text book to get a 3 phase motor running when only 1 phase was available. The live and neutral was connected to two phase inputs and from these terminals two capacitors were connected to the third phase. I think standard 1 phase starter capacitors were used. Of course, the power output is well below the rated output due to the lower voltage.

However, I have never seen this in practice, since over here the 3 phase feed comes to nearly every building.

I have had an IC706 MKII for a couple of years.

I just recently bought a power gage to my antenna.

I discovered that my microphone, that comes standard with the IC706
MKII just exites the trx to 2 watts of output power! It should be 100w
(or something like 100/sqrt(2) !

No wonder people have difficulties hearing me.

I have heard that this microphone can be modified to produce a better
result.

Does anyone know how to do that?

Please e-mail me in that case:

==========

Normally I don't respond to offers like the above ,but on this occasion I
feel I have to react.

The EL37 is a pre WW II pentode used in the output stage of domestic
(broadcast) receivers with an output of up to 11.5 Watts . (Va =250 V ,Ia =
100 mA)
As far as the asking price is concerned Arnold either made a decimal error
(we all do from time to time) or he tries to take the amateur community for
a ride . Even US$11.30 seems on the high side for this type of
valve..... Hope that Arnold ,in future,will offer his ware at
more realistic prices.....at least on this NG or perhaps even better
.....not at all !

That's a simple task in a BX-24 (http://www.netmedia.com). You can easily time the pulse and generate a calculated 10-bit analog voltage between 0 and +5V with standard instructions in pseudo-VisualBasic.

> Sverre Holm
==========
The German frequency (from a tx in the Frankfurt a/M area) is 77.5 KHz

In the UK & USA the frequency is 60 kHz , in the UK from a tx at Rugby
in the Midlands - England

Although the range is up to 1000 km for these clocks to work reliably ,
clocks receiving 77 kHz seem to work well in most areas of the UK.

I use a make Zeon Tech clock made in Germany ,but receiving Rugby @ 60 kHz

The accuracy of these clocks is based on a 'Caesium Clock' , I believe in
the UK located at the National Physics Laboratory , NPL.

Hello,

I am an artist who is working on several sound pieces. I need broadcast equipment for them. The tow project require

1. several FM mono transmitters that will have the following qualities:

1) Will be stable
2) Will have a range of at least 1000 feet (longer would be great)
3) If a kit will be easy to assemble, I can solder, but not terribly well, I would prefer something pre-assembled.
4) that will be reasonably cheap, I am a student

AND

2. a stereo FM transmitter that will allow me to do longer ranger broadcasting ala LPFM. With the same attributes as above in terms of ease of assembly and use.

If any one has any suggestions I would love some words of wit and wisdom. I want to find a reputable place or person to do business with.

Thanks! PLEASE E-MAIL ME!

Richard Holland

If you just want to use them, there is a schematic out on the Drake List homepage for the cable set and interface. If you want the actual Drake parts, keep looking. Of course, you couls do both, in which case the URL is: http://www.zerobeat.net/drakelist/. Look in the mods section, or the tech notes. You could also ask in the message board. It's a great place for Drake owners. I envy your RV-75 and R-7. Be sure to let me know when you want to sell them!

I just installed a yaesu ft90 in my b5.5 (2001.5) VW passat.
So far no one has complained about me on 2M. I will tune the AM air bands
on my way home and let you know how reception goes.

The annoying part with the install is that I didn't see an easy way to
run wires from the battery. I didn't try very hard either. So I did
the dubious step of getting a 10A rated cigarette lighter plug with
banana posts from Rat-Shack and hooked my rig up mounted in the trunk
with the trunk's power-plug. Supposedly my rig won't draw more than 9.5
on maximum transmit, not that I plan to ever do the maximum...

My travels through the web have shown me lots of people who are having
trouble doing that task plus others with various microprocessors. A
processor might even be a fun way to do this; but the project this goes
into is already enough work without acquiring development/programming
boards and learning their quirks and the quirks of the processors, etc.

I could also gate a biased counter to do this digitally, latching the
count at end of pulse. But by the time I do that, I end up with more
parts (and lots more nodes) than the analog solution I proposed, which
my gut tells me is already overly complicated for the task.

development/programming boards and learning their quirks...

The processor is just another designer's tool, albeit a very powerful and flexible one. Yes, new tools require time to master, but the monetary costs are $200 or so to get an evaluation/prototyping board and a processor or three; the programming environment is gratis. A few days later you'll be moving an analog signal through the thing and you'll be hooked. If you had that tool in your repertoire I'll bet you'd not think twice about implementing your PulseWidth:Voltage project in BX-24 code rather than holding a linearly-ramped voltage; it's a natural for the part and a good starter project.

From: CJ <cjr@visi.com>
Message-ID: <3AE22602.3331692@visi.com>
Source record: 53203

Three things come to mind. I have the original IC-706, so these things may not apply to your radio, but I rather think they might.

1. The microphone is a noise cancelling one. That means that one must speak very close to it. It should be held right up to the mouth. Otherwise, it will pick up your voice from both the intended front grill/grating and also from the background input and you will tend to cancel yourself out.

2. There is a microphone gain control item on one of the menues. Look it up in the book. There is also a power output item. Be sure it is set to maximum. Remember that "average peak" power output on SSB as measured by a mechanical (D'Arsonval) meter is likely to be only about 20 - 25 % of the true peak power. Maybe less. It depends on whether or not compression is used and also on individual voice characteristics. A whistle into the microphone will often produce something appoximating the real peak output on a meter.

3. The overall gain of the radio varies from the lower frequency bands to the higher. I find it hard to get much ALC response on 10 meters, but with the same microphone gain settings, I get a big ALC response on 80 meters.

i have obtained a rf amp from the flea market for the price of $20. it is a "killer bee" dx 250 hdv. it was presented as never used, and by all appearances that looks to be true. i am not familiar with this equipment and would appreciate a lesson on the function and proper use of this thing. since this group is full of hams, i thought someone would help me. there are five controls and one meter. three are on/off push buttons. they are power, rec amp, and am. one is a rotary knob like a volume control. it is marked with "min" to "max". one is a rocker switch marked "ssb on/off". the meter is marked "rf output" and has a one to ten scale. most of these controls are self explanatory, but what does the "am" button do? what kind of power is the input supposed to handle? and what is the power output of this thing? are filters built into this amp to control harmonics, or is that an outboard part? what frequencies does this operate on anyway? i know that i need a license to transmit, so (respectfully speaking) please spare me the lectures. i need knowledge, not moral guidance. if this proves to be interesting then i will have more incentive than ever to try amateur radio. i guess having an amp is a start!

2508. # 61 ferrite material ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-22 12:19:12 UTC
From: amdx <amdx@att.net>
Message-ID: <4%zE6.30268$RF1.2522729@bgtnsc06-news.ops.worldnet.att.net>
Source record: 53202

During some experimentation I have turned some #61 ferrite toroids on a lathe.
They turned fairly easy, no problem.
I pulled the ferrite rod from three different portable radio in an attempt to find
a rod that I could turn with the same ease of the toroids. None of the rods seemed
to be the same, it was a harder material, it turned to a rust color with shiny metal
flecks mixed in.
I thought #61 was the material choose for most AM loopstick antennas, is there sonething I'm missing?

Mike

2509. where to find QST on CD

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-22 13:38:02 UTC
From: pdrunen@aol.com
Message-ID: <20010422093802.10317.00000445@ng-ci1.aol.com>
Source record: 53204

Hi Group,

Is the old issues of QST available on CD?
I do recall seeing them a few years back but now can not locate them on
the http://www.arrl.org or amateur electronic supply web site.

Thanks,

Paul

2510. Re: off topic, 10 meter amp?

This is very curious.

Searching the web I came up with a few references that seemed to indicate that this is a 250 watt out, 5 watt in CB amplifier. Amplifiers of this type are illegal to manufacture or sell in the U.S., except that licensed amateurs have an exception where they are allowed to construct one a year and may sell it to another licensed amateur. There is no prohibition on buying one of these, however. The pictures that these CB articles linked to looked just like I would expect such an amp to look like, and looked kind of like you describe. One of these CB links indicates that this is a 4-6 watt input, 250 watt output amp. Exactly what you would want for illegal CB operation.

However, further searching led me to the manufacturer's page (http://www.texasstar.com/CW.html). The manufacturer calls this a 5 watt, crystal controlled CW transmitter! The description refers to semi break-in keying and an onboard receive preamp. Curiously, the manufacturer's page never once mentions QRP (as you would expect a 5 watt transmitter to be targeted at). Also, QRPers tend to be battery conscious, and the heavy use of incandescent lamps (power hungry) would be inconsistent with what this market would demand.

There are 4 models listed on the above page, and it isn't clear to me what the differences between the models are, other than the HDV models have a break-in delay rocker on the rear instead of a pushbutton on the front, the break-in pushbutton being replaced with a power output pot. There are an additional 6 models on another page that also appear to be the same thing, except for higher current consumption. The CB page (http://jmpaintball.homestead.com/ampspowersurpplys.html) seem to show these as all different power output amplifiers.

The manufacturer's page shows 3 or 4 buttons on the front panel, none of them listed as 'AM' as you describe. I'm curious if the pictures are similar to what you have.

The manufacturer's site includes a schematic which, at first glance, doesn't seem to support it being an amplifier. However, the size of the heat sinks in the pictures are excessive for a 5 watt transmitter.

Your $20 price would be consistent with a used 5 watt QRP transmitter - CB pages show used prices around $200, more in keeping with an amp.

In either case, this is a 10 meter device, whether a transmitter or amplifier. I would hurry up and get that license. The sunspot cycle has peaked and in a couple of years the 10 meter fun will fade for another decade. Right now, tho, 10 meters is great!

Any similarity to a 5 watt CW transmitter and something made by Texas Star is purely coincidental and intentional on their part to try to keep them from being put out of business by the FCC. Note the 30 amp fuse in the diagram and a bit of scrutiny will show that the circuit is such that it requires no effort to make it a high power illegal CB amplifier. Let's hope that the one bought for $20 isn't put to use in this manner. If the buyer so intends, let's hope the transistors were burned out by a CBer too stupid to hook up the power with the correct polarity.

For those who ARE LICENSED and care and want to keep the CBers off 10 meters with high power, a note to:

FCCInfo@fcc.gov

complaining about Texas Star might help get them shut down.

This company must think they're smart to disguise obvious amplifiers as CW 5 watt transmitters! Yeah, SURE, and I have a bridge formerly called the Brooklyn Bridge that you can buy from me cheap and rename it however you wish and charge tolls on it.

2517. Cutting a branch

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-22 16:17:52 UTC
From: John O'Flaherty <oflahert@toast.net>
Message-ID: <3AE30430.2193075F@toast.net>
Source record: 53212

Yesterday I cut off a branch that had been interfering with my wire antenna. It was too high to climb to, and too high for a pole saw, and too unimportant to rent one of those lifts ($100 for just a couple of hours). I used a rope saw, which I made by using a grinder to cut one link of a chain saw chain. Then I used a slingshot, fishline, and rope to get over the limb. I attached the chain saw to the rope by making a loop knot at the end of the rope, and then pulling the end of the chain through the rope loop, and making a loop of the chain with some 20 ga. copper wire twisted through it. Then the same on the other end of the chain, and I had my rope saw. I got it up over the limb, and sawed back and forth for a few minutes, and then it jammed, and wouldn't loosen until I had pulled hard enough to separate the rope, and then the whole business came down. I could see from the traces of wood on the chain that it had been sawing on the wrong side. It sawed for a couple of minutes, until the wider part of the back of the chain hit the limb, and then it jammed.
After getting the rope back over the limb and reattaching the chain, I put a piece of fiberglass tape around the end of the chain as a flag, such that it stuck out from the back of the chain. Then, when I pulled the chain over the limb, I was able to see the direction of the flag, and twist the rope enough that the chain went over the limb in the right orientation. Then it only took about ten minutes of sawing to bring down the 3-inch diameter limb.

Thanks for replies.

The DCF77 station transmits at 77.5 kHz, more information can be found at
http://www.eecis.udel.edu/~mills/ntp/dcf77.htm
and http://www.dcf77.de/ .

My interest came because I intend to modify an old receiver that has the long-wave band (150 - 350 kHz) to a lower frequency to receive the amateur band at 136 kHz. I think this is easy to do by just adding some capacitance to the tuning and oscillator circuits. I was hoping that I also could receive DCF77, but I think the difference in frequency is too big.

Yup,

Anybody with any radio "savvy" will know what this thing is! I visited
their site recently and got a laugh out of how they are "masking" their

illegal product. For example, the DX 1600, mostly known by CBers as the "Sweet Sixteen", has 16 transistors (in the 11 meter vernacular known as "pills"). Imagine! Sixteen output transistors for 5 watts "CW"! Also notice the label on the lower right corner "SSB Delay". Hmmmm.....sideband delay? HA!

2522. Re: off topic, 10 meter amp? **ILLEGAL AMP***

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-22 18:41:09 UTC
From: WB8RCR <wb8rcr_NOSPAM@qsl.net>
Message-ID: <9bv8kh01qod@news1.newsguy.com>
Source record: 53218

The schematic certainly is interesting.

There seems to be no sensing of RF on the 'radio' side, so it would be clumsy at best to use it as an amplifier, assuming the schematic is correct. There is an oscillator, as described, and a keying transistor which senses the oscillator to enable the TR relay. All of this would seem to support the 'CW Transmitter' claim.

However, looking a bit more closely at the finals, it would seem to be a bit of overkill to use 2 120 watt transistors in the final of a 5 watt transmitter! These are fairly expensive transistors. There also appears to be no SWR protection circuitry.

However, on another page, Texas Star shows the 'export' version of this transmitter to be an amplifier, 250W SSB or 120W AM.

And finally, Jim, getting back to your question of the AM switch. The schematic shows no such switch. However, on an amplifier that would be a useful thing to have. The reason is this ... on SSB, the output transistors only need to generate RF during a tiny part of the cycle. SSB transmissions have no output when there is no sound, so the overall duty cycle is no more than 50% when there is a sound, and 0 when not, so overall the actual duty cycle the transistor sees is on the order of 10-25%.

On AM, however, RF is being generated all the time at almost the full output. A switch which reduced the output on AM to prevent the transistors from being toasted would be a useful thing! In addition, there are some technical differences which would allow an amplifier to amplify SSB somewhat more efficiently than AM.

Not to rain on your parade, Jim, but this sort of amplifier is of relatively little use in amateur service. There are a couple of reasons for this. Firstly, 5 watt 10 meter transceivers are fairly rare. Those that do exist are generally intended for CB service and cost a lot more than 100 watt transceivers that can't be easily modified for CB. These also tend to be relatively low quality since the larger manufacturers are going to quickly become targets of the FCC if they make a transceiver that is purported to be for amateur use but is, in fact, aimed at the CB market.

The second reason has to do with the nature of 10 meters. 10 meters is the high end of the HF portion of the spectrum. When the band is open, it's quite easy to communicate worldwide with just a couple of watts because the atmospheric absorption is so low at that frequency. In addition, the atmospheric noise also tends to be quite low. I've personally worked all continents on 10 meters using less than 5 watts and a homemade antenna made from $50 worth of conduit. When the band isn't open, you can communicate

essentially line of sight no matter what the power. Tremendous increases in power can get you a little bit beyond line of sight, but not enough to make it worth the hassle. When you've worked Australia and Africa it's not much of a thrill to crank up a kilowatt to talk 50 miles away!

This isn't the case with CB. On CB, the band is channelized and receivers are built to accommodate the relatively wide requirements of AM. On CB, you are almost always talking over someone else, so the station with the most power wins. On the amateur frequencies, especially on 10 meters which is a very wide band, there is almost always a place between other stations, so you don't need to interfere with someone else, and it's not considered very good form to do so! So with no other stations to compete with, you don't need the power.

Again I would encourage you to get that license and get on the air sooner rather than later. The solar flux is low this weekend, so 10 meters is dead. But by next weekend the active solar region will have rotated into view, and 10 will be open again.

Meanwhile, I hear an EA7 (Spain) calling CQ on 20 - I think it's time to get on the air and off the Internet.

They make a "wire saw" for backpackers and outdoors 'people'.
It's hard to describe -- sort of a tightly twisted ss band
with 'chips' of Very Sharp metal bonded to the full length.
It has two finger rings at either end and is about 19" (50cm)
long. It would work Quite Well in the lash-up you've described.

yes, the picture at texas star site is exactly what i have! thanks for your help, but now i am more in the dark than before. what (technically speaking) is the difference between the illegal 250 watt amp and the qrp 5 watt transmitter? if it is a cb amp then wont it also amplify a 10 meter transceiver the same way? if used for cw then how is it used and what equipment is needed to excite the transmitter? is this a noise making piece of cb junk or is it a useful piece of equipment? is there a good source of knowledge that i could read to start me from the beginning so i can figure this stuff out? and why is there always someone wishing harm to my transistors? i suppose that i could leave it at a truck stop like an abandoned baby, but i was trying to find the PROPER use for it. the cb problem is not a problem because i dont speak "retard" (tardish?), the language in common use on the cb band. i just have an intrest that i want to satisfy.

first, to clear any confusion let it be understood that "babbit" is my wifes account. it was still me in an earlier post. the consensus of my private e-mail responses leads me to believe that this amp must be useless cb junk. i am slightly disappointed but i got what i wanted, answers. now let me eat crow here. i said that i didnt need moral input, but now i am asking for just that. as HAMS, and knowing that this useless junk has more value when used illegally, would you throw it into the parts box or would you put it back into circulation? i could possibly trade it for something useful if i gave it to a cb nerd. on the other hand, it would then be turned into a weapon of mass rf destruction and used against innocent hams who are minding their own business. am i responsible for the radio wreckage that this cb amp might cause even if i am not doing it myself? and if i am then would that outweigh the legitimate receiver or something that i might be able to trade for?

Why? Based on a random sampling of various models I'v run acros,, in
general most of the ones I've tested were very poorly engineered.
Inadequate heatsinking, poor bias regulation (if even an attempt at
linearization was made!), and no harmonic filtering on the output.

Good luck to you if you get one....

Pete

Bob,

With some care it should work.

Since the frequency accuracy does not have to be to good on your
sources you might try using simple L/C oscillators.

Hey, you only spent 20 bucks for it. Part it out and maybe one day you will
be able to use the parts in something worthwhile. Many of these junk CB
amps used decent RF transistors, which could be better used to build or
repair a quality RF device...

Personally, I would homebrew an exciter for it, but then that's just me.

Looking more closely at the schematic, it appears it would need to be modified to operate as an amp, but it would make a very dirty transmitter. I can't see where, as a transmitter, this thing could possibly comply with 97.307(d), even at <5 watts. However, as an amp, if not overdriven, it *MAY* just be OK. Hard to tell without testing. Does look a tad dicey, but with hand selected components, as indicated in the schematic, it may just be possible. Of course, this all assumes that, for some strange reason, the schematic is more believable than the specs!

I'd find a local ham with a kilowatt dummy load and some test equipment and see what the thing is actually made of.

If you could put a little filtering in the output, the thing may well make a dandy little CW transmitter. It has the TR switch built in, so it ought to be useable with any sort of receiver. On 10 meters, you rarely need much in the way of selectivity, so a fairly cheap receiver may well get you on the air. Rockbound is kind of a drag, but hey, something is better than nothing.

Source record: 53230

I am just trying to simplify and miniaturize a RF remote control receiver of my design with a latched and momentary output. I am now using a 4013 Flip Flop 14 Pin Dip Package. I am looking for a 8 Pin or smaller thru hole or preferably a surface mounted package with a latched output and requiring no external debouncing blackmagic. I cannot use a HOLTEK ic for this application. An optoisolator with a latch on off output would work well .It would also have the added advantage of voltage isolation, noisy mechanical switch input, transistor high and low input, analog or digital input. Does anyone make such a device? If not, I wonder why not.

They could possibly also add a momentary output along with the latched output.

To see a picture of what I am talking about go to the following web site:
http://members.aol.com/skresse13/output.jpg
My picture speaks a thousand words.

Believe me, I have nothing against uPs. I helped write an A/D routine for
the 8048 back in 1981, and I've done my share of embedded systems work for
clients. Fact is, I've done enough of that kind of thing to know that
between learning a new instruction set, acquiring the gizmos and learning
the compiler/assembler/linker/loader quirks, I'll add a month to this
project. (Using a BASIC Stamp would almost certainly require using it
solely for this one function, judging by the problems others report with
doing this very function while others are running.)

This is not to say I won't eventually commit to a processor (the PIC looks
neat, cheap and suitable) and get down to brass tacks with it; there are
too many nifty things to be done. It's just that this particular project
doesn't allow me enough time to do it now, and will be eating the budget
that would otherwise pay for the development stuff.

2537. New project: 17 meter DSB TX

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-23 10:02:07 UTC
From: n2cqr@clix.pt
Message-ID: <3ae3fa80.1409924@news.clix.pt>
Source record: 53231

I feel the urge to melt solder. And I want to build a "phone rig." I've always wanted to get on 17 meters (no contests!). I can listen to that band on my Drake 2-B. Here's my plan:

Solid State Doouble side band surpressed carrier TX based on Doug DeMaw's circuits. Very simple. Sort of a direct conversion transmitter. The oscillator will be on the transmit frequency. I think I'll start out with a VXO (I have the rock). Solid State PA. (Another option I considered would be to put the boards on an old DX-60 chassis and rebuild the 6146 PA stage... but I think that might be overkill.)

I'm going to start out just building a transmitter. I'll build the oscillator first, then the DSB generator. Finally (!) the PA. I'm going to leave room in the cabinet for receive circuitry. It would be very easy (and sort of appropriate) to build a matching direct conversion receiver, but I've had bad luck with them and may decide to build a real superhet RX and make the final rig a Transmitter - Receiver (not a transceiver).

I have an old Bud cabinet that's about the right size. I'm thinking of using the Manhattan technique on the circuit boards.

What do you guys think? Anyone out there built this kind of rig?

This person won an ebay auction of mine. Read it below:

Db Products Six Cavity Duplexer VHF I don't know much about this
duplexer, other than what I was told. I got it from a Ham
who said he had it on 146 MHz and it goes from 146 to 174 MHz. And he
said it works fine. It has a manual for it. Being I
don't have equipment to check it, I have to sell as is, so please bid
accordingly. Sorry, Thats all I know and can't answer any
questions, I'm not a tech. Winning bid must pay for within 6 days of
auctions ending with Postal Money Order only. Sorry, I
don't do paypal or anything else. Winng bidder must contact me within
24 hours with mailing address. I ship UPS only. USA
bidders only. Shipping UPS Ground is a fixed price of 30.00 Shipped
And Insured. Thanks and Good Luck To All!

After he wrote numerous emails BEFORE the auction ended, I reassured
this person that I did not know anything about these. That's why the
auction began with a $1 opening bid with no reserve.

I also stressed to him numerous times to PLEASE bid accordingly that
this item is AS IS and I have no further info about them. I told
him that I personally could NOT check them.

He won the bid anyhow, and now has the item and is not happy. He
called me on the phone harrassing me and sent harrassing emails.

On the auction, I also posted several pictures of the duplexers for
bidders to view.

Richard Gillani is a complete nuissance and I would like to warn
others out there that may be selling to him. Watch out. He's a bad
penny. His Email address is: tbolt@ix.netcom.com

This will be my only posting because I will not waste these boards
bickering back and forth. My position has been stated here.

Thanks for reading this.

He goes by one of these two calls AK2K or W3RJG at the same
address which is: 3084 West Seneca Turnpike, Marcellus, NY 13108

2540. Re: # 61 ferrite material ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-23 12:00:39 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3AE41967.B4248F26@eznec.com>
Source record: 53237

Ferrites are ceramics, and I believe there are three common basic ceramic types used -- the 70 series is made from one, the 60 series from another, and type 43 from a third. They have somewhat different properties but all are hard and brittle. Being ceramics, they're all homogeneous, and they're all dark gray in color. The material you're describing from the rod, metal flakes in a rust-colored binder, sounds like powdered iron, not ferrite. But I'd be surprised if powdered iron would be harder than ferrite, and I've never seen powdered iron used for a portable radio antenna. Maybe somebody else has. So I'm mystified by what the rods are made from, and also that you've got something that's noticeably harder than #61 ferrite.

I'm pretty sure portable radio antennas would more likely use 70 series, type 43, or similar ferrites rather than type 61.

You can order them directly from the ARRL:
http://www.arrl.org/catalog/index.php3?category=CD-ROMs Ham
Radio Outlet (http://www.hamradio.com) also sells them; they're
listed on page 47 of their catalog, which you can view online in
PDF form.

The ARRL page mentioned above shows all the ARRL CD-ROMs,
including the QST View series. The QST View CD sets (either three
or four CDs, depending on which years you buy) contain
black-and-white scanned images of five (1960 and later), ten
(before 1960), or fifteen (the 1915-1929 set) years worth of QST.

QST from 1995 and later are on the ARRL Publications CD-ROMs.
Each annual CD contains all the issues of QST, QEX, and NCJ,
including color illustrations, and offer full-text search.
(Unlike the QST View series, they contain the text in electronic
format, rather than scanned images.)

==========
Listening to a local AM medium wave BC station with a Ten Tec ,Paragon on USB and LSB , provides very clear reception , although the sound quality on LSB is the best (must have something to do with the settings of the side band filter). I often do that on other AM (full carrier)BC stations ,also on the short wave bands.

For home brew projects DSB is ideal ,since with a balanced modulator the carrier can be easily suppressed ,whereas no (costly)sideband suppression circuitry is required .
I agree that in crowded bands DSB is considered anti-social ,but the bands are not always crowded.

My conclusion : DSB is an excellent 'home brew' option especially for QRP operation.
Thought I should post this on the Home Brew NG.

I wish I had known- I checked Home Depot tool department but didn't see it. Maybe it's in the plumbing department. In any case, the setup I have should be good for a few more loppings.

I am sure an enthusiastic home brewer would be able to make a good 6 m power amp from this CB kit ,provided the power transistors (perhaps even MOSFETS) would be suitable to operate on 50 MHz.

2548. How do you repair headphones w fiber/wire

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-23 16:19:24 UTC
From: Frank Sweeney <fsweeney@mail.com>
Message-ID: <HFYE6.3$gn.1727@nntp0.chicago.il.ameritech.net>
Source record: 53243

Gentlemen,
A few months ago I saw an article on repairing headphones which uses the unsolderable wire with the fiber threads in it (I guess the fiber is makes the cord more flexible). The article I thought was online but I could be wrong talked about using a crimp type of connector which the author was surprised that radio shack still carries that would piece the insulation of the wire making contact and then allowing the pin of the connector to be soldered to the new audio plug. The author even went so far as to give the radio shack catalog number for these connectors.

At this time I thought I would be able to remember where this information was for future reference..but you see that's the problem with getting old.. you think you can still do things and you CAN"T! I should realize that now that I am over 40, I suffer from CRS (Can't Remember Sh%#) and start taking notes. The only problem w this idea is that if I take notes I won't remember where I wrote it..so that wont work either.

If anyone has any ideas on how to put audio connectors on this crappy wire please let me know.

73,
Frank - K9IC

> Hey Guys - any help on this subject would be greatly appriciated by me
> as well. I do OK on 2 meter (noisy though) but AM is a mess in my 99
> New Beetle 1.8T. Also being an aviation buff I like to listen to 118 -
> 132 mhz AM when I go over to trhe airport (Unicom, Atis, Air Traffic
> Control, etc) This particulat frequency is unuseable in the car...
> sounds to me like Ignition noise.....

The first thing you need to do is determine if the noise is coming from the power source, or is being radiated into the antenna. Unhook the antenna, tune to AM and turn on the rig with the engine running. Vary engine speed and listen. If you still have the noise, and it varies with the engine speed, then you will want to filter your power (which is coming directly from the battery, yes?) This is the easy problem.

If there is no noise when you unplug the antenna, then the real fun starts. Something is radiating RF into your antenna system, so you will have to track down what it is. There are any number of things that might cause it, including fuel pump, spark plug wires, alternator, engine computer, etc. You will just have to isolate and eliminate each one as a possible cause, and go on to the next.
Some of the possible remedies include filters (isolation caps, notch, etc.), wrapping aluminum foil around an offending part, braided mesh over wires, and so on.
The first and best solution, though, is to make absolutely sure your whole system is well bonded to the car. Run a braided strap from the radio to a structural connection (mine goes to a bolt that secures the passenger seat). If necessary, run bonding jumpers from the body panels to other panels, and the frame. Make sure that you are getting your DC direct from the battery through heavy gauge wire. Keep connections short.

If you can find it, the January / February 2000 issue of QEX had a good article about eliminating mobile noise. Let me know if you need it, I can provide you a copy of the article.

> If anyone has any ideas on how to put audio connectors on this crappy wire
> please let me know.
> Frank - K9IC
==========
Use AMP or other make crimp connectors. The through crimp connectors are
suitable .
On one side of the connector you can crimp the 'crappy wire' , on the other
side you then crimp a short piece of multi-strand lead to which you solder
the audio connector.
The RED connectors are for approx 2 millimeter (or inch equivalent) wire
,the BLUE
connectors for approx 3 millimeter (preferably multi-strand) wire. In the
UK these are available from
car component outlets . Suggest you use a proper (low cost) crimping tool
,which should only cost a few $$$

I use crimp connectors for many electronic applications . Especially the
fully shrouded 'bullet' type crimp connectors are suitable for various
applications like for a speaker inside a transceiver which might have to be
temporarily disconnected to be able to take off the lid of the enclosure ,
or internal/external power connections , etc.

If you have a problem in finding the crimp 'through' connectors , I'll be
happy to send you a set of BLUE connectors for your headphones application .

yes wonderfull ebay. although i have made a few good deals with some
really decent people there are those that.
1. dont reply to your emails after the deal
2. you have to ride their ass constantly in order for them to ship
anything out
3.and the as is seller who knows damn well that his gear is junk.
although in your case you have made it very clear what condition the
item is in. i finally decided after much hairpulling and 45 day shipment
deals that goodbye ebay and stick with the reflectors for buying and
selling. as far as as is condx if a item dont work when i get it oh well
i either fix it or strip it for parts. good luck in your ventures

Easy. Wrap the tinsel wire with very fine copper wire, either stripped
wire-wrap wire or a single strand from an AC line cord. Wind the wire in an
even smooth solenoid layer over the exposed tinsel cord. Heat and tin.
Insert in a phono pin if that is how you are going to terminate them.

Good luck.

Pete

Hi Frank,
I won't dispute that DSB would be fairly easy to implement in homebrew.
As you picked up, I was just commenting on the fact that modifying a
commercial rig to run DSB, and I assume the original poster was using it
in crowded bands, that it was anti-social as you describe.

I want to attempt to do a calibration to my HP-1722B 275MHz analog scope. According to the service manual the instruments I need which I do not have are a pulse generator and a time mark generator. Is it at all possible to somehow use audio frequencies (for example software used on my computer sound card) to mimic a pulse generator and time mark generator)? If so, does anyone know of shareware available that would run the sound card as pulse and time mark generators?

If not, does anyone out there have any other suggestions as to perhaps a quick and dirty method of scope calibration?

Your assistance would be greatly appreciated. Thanks.

Dittoes.

I've also done my share of dumping the fragile cords and replacing with
something more substantial. On some recent projects, Ive taken to using
4-pin handset mod plugs and plug-in telephone handset cords. Replaceable,
available in different lengths, colors, etc.

Unless someone has monkeyed with the alignment adjustments I wouldn't think it would be necessary to do much more than check the calibration of the gain and time base.

If that is the case, you can use a short wave receiver and any test oscillator to verify the time base at high speeds and the 60 Hz power line at low speeds. The voltage calibrator which is internal to the oscilloscope (I believe there is one) can be set with a voltmeter usually.

```
-----BEGIN PGP SIGNED MESSAGE-----

Hi all, I acquired an old Icom IC-22 2 meter crystal tuned transceiver
and am trying to get it restored running. I do have a few crystals that
came with the radio and know it works, but would like to install some of
local frequency pairs for my use. Both Tx & Rx frequencies are crystal
tuned, I just haven't had much luck locating what I need and figure it's
time to ask the masses.

The specs in the manual call for:

High Activity
HC-25/u Holder
0.0025% Calibration
20 pF Load Capacitance
15 ohms or less Load Resistance
18.0000 to 18.5000 mhz for Transmit Fequencies (Tx Freq / 8 )
14.8111 to 15.2555 mhz for Receive Frequencies ( [ Rx - 10.7 mhz ] / 9 )
Cut: "AT" optimum angle +/- 2 min.

Recommendations, links or miracles are welcomed, Thanks in advance.

Source record: 53170

Tony,

The major reason behind tube construction rather than any other is strength. A tube will be self-supporting. A tube also gives the largest surface area of any other geometrical shape. There is no reason you can not use a flat strip except for support. If you can figure out a way to support a large structure of strip you will be OK. \

Most of the seminal articles on building and using loops were written in the early 60's. The purchase of a couple of QST CD ROMS from that period will provide you with lots of ideas. Well worth the cast. The individual articles may also be available from ARRL Headquarters for some nominal fee.

Coupling via loop or other method seems to depend on the time of the day and the weather! I have sued both, a "gamma matched" coupling at 2 meters and a loop at HF. Frankly I could not tell the difference!

Also the matter of inside or outside for the capacitor is also an area where your own design will work best. I don't think there is any overwhelming reason to put it in either location.

The antenna should be considered experimental and thus, whatever works will be the best solution for you! Build it an make measurements, even simple field strength measurements will tell you a lot.

Like Bob, K6DDX, said "Unless someone has monkeyed with the
alignment adjustments I wouldn't think it would be necessary
to do much more than check the calibration of the gain and
time base".

The problem you have is that, even if you were to get a marker
generator and a pulse generator, how do you know how accurate
these instruments are? Where is the reference? When were the
generators calibrated?

Unless some parts were replaced or the alignment controls
were changed, the accuracy of the scope is not going to
drift very much. I have used a lot of HP and Tektronix
scopes and they have always been very stable and accurate.
It will probably stay more accurate than you, or I, can
visually resolve from the screen.

Source record: 53173

I hit the store (Active) and found both XR2211 and XR2211A on the shelf; the A part was 50 cents cheaper. So I hit their data book and it didn't show an A part, much less a distinction. So I bought the A parts anyway.

I just went to their site, which won't give me the datasheet unless I jump through hoops. But I got some confusing data anyway. The leadin page says the A part is good to 25 MEGAhertz (vs. 300 KILOhertz for the non-A); but when you ask for more, the next page says it's 300 KHz. Anyone know which is true? I can think of several uses for a 25 MHz 2211.

Cliff,

The "A" part is the slightly relaxed specification version. The main
difference is that the 2211 part has better temperature stability (50 PPM)
than the "non-A" part (100 PPM). Both are rated to 300 kHz.

I am sending you the data sheets (Adobe PDF format) in a separate message.

: Chris
:

I built a ham doppler speed measuring device when I was in high school in the early 1970s. It was a single 5" horn with a "magic tee" coupler. I used a 2K25 reflex klystron (stretched to work in the ham band) and a home brew power supply. The receiver was simply a waveguide with a diode mount and lots of audio gain. I built an audio frequency meter from threshold-crossing detector driving a pulse generator driving a large capacitor across a meter (leaky integrator). The meter was calibrated in MPH. Frequency calibration was with letcher wires (sp?) and speed calibration was with a calibrated audio frequency generator.

Larry, does your scope have a square wave test signal output? normally they do and can be used to cal both vert and horiz features ,if not ,you can use a precision vm and an audio gen and counter to cal vert and horiz.of course if you use rms signals you would need to do a bit or arithmatic to convert to peak to peak.scopes are usually no better than about 5%accuracy at best..good luck Harold

From: w9wi@linux1.localdomain
Message-ID: <slrn9ecklf.c85.w9wi@linux1.localdomain>
Source record: 53180

Thanks to Roger Leone's advice, I was able to repair my MMT144-28 transverter this morning. But after getting the replacement 3N204 in the RF amp & working (and clearing a mystery VCC short...) I had to get the tuned circuits realigned.

Unfortunately, I don't own a VHF signal generator. I could have used a 145.23 repeater about 50 miles away, but continuously kerchunking a repeater for 10-15 minutes probably wouldn't have made me any friends<grin>. Besides, I'd rather this thing peak at 144.2 rather than 145.2.

Tried firing up the hamshack computer & looking for clock harmonics - no luck. I guess the feedline on my 2m antenna is too well shielded...

Then it dawned on me: I've got a programmable scanner. Lessee, what's 144.2-10.7? 133.5. OK, let's put that in the scanner & see what happens. Sure enough, a weak but stable (but with rough modulation!) carrier on 144.2, which allows me to quickly line up the transverter.

I *was* surprised how "dirty" the scanner's LO signal was. Strange that it doesn't impart ugly modulation to received signals.

Those who may wish to duplicate this experiment should be aware that not all scanners use 10.7MHz for the IF; 10.6 and 10.8MHz are also occasionally seen, as is 21.4.

Now, all I have to do is scare up some 2m SSB activity around here!

2587. LOW cost Pre-amp circuit ideas?????

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-25 06:06:25 UTC
From: Jim Bo <jbollit@ix.netcom.com>
Message-ID: <3AE66961.DE19F964@ix.netcom.com>
Source record: 53181

Hello,

I want to build a LOW cost pre-amp that will work from 850 MHz to

870 MHz range. I am concerned about overload of the pre-amp with

cell phone transmissions.

I am going to build a collinear vertical antenna (eight elements)

and put it in a fiberglass "tube" and pot it using epoxy potting
compound.

I want to mount a LOW cost pre-amp right at the feed point of the

collinear antenna, inside the fiberglass tube. The inside
diameter of the tube will be 0.5 inch or less.

I will power the pre-amp through the coax.

Doesanyone have a simple low cost circuit that I could use?

Thanks in advance

Jim

Yeah. Use hardline instead of plastic coax for the feedline.

2592. Pll loop filter values...

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-25 20:06:23 UTC
From: Kari Back <kba@nic.fi>
Message-ID: <3AE72E3F.52476680@nic.fi>
Source record: 53189

Hello...

Having done experiments with triple loop pll for 906-914kHz final output, and
fine tune reference 106-114kHz and with coarse step 100 kHz, offset VCO runs at
800 kHz.
Kvco is low ~0.25MHz/V, op-amps used after D-FF phase detector.

Both VCO's make lock and seems to be ok, except the locking condition seems to
be too critical... probably fine loop filter constants are not valid...

Can someone give tips please for the fine loop filter values ?
(Before ordered literature arrives from bookstore...)

You can download the free PLL2 and PLL3 design programs from
my web site at:

http://sites.netscape.net/kd9jq/hamradio/kd9jq.html

The programs and included manual should be helpful in
working up values for 2nd and 3rd Order Loops.

Hey Scott,

<more seriously this time>

I reviewed some double sideband material. To summarize:

*It is cheaper to build (for budget homebrewers)
*It does consume and transmit a bit less power (No Carrier)
*The signal to noise numbers are a compromise between Am and Single
Sideband.

Modifying a ssb transmitter to transmit dsb does seem kinda silly. Receivers
that can detect dsb can detect ssb. Its not like we have to transmit dsb to
work the those HB dsb rigs. Like you... I'd just as soon go all the way and
get rid of that extra sideband. Better performance and better manners, too.

Never mind about Nobel... there ain't any new math.

Source record: 53100

I have built the FM transmitter on this side.

http://www.avlyssning.nu/fmsandare/stationtransmitter/4/index.htm

It is supposed to output 3W, but I have only measured roughly 0.5W-1W. Could anyone please give any tips on what to do to increase the output. Can I change the bias on the power transistors?
Input current is about 250 mADC.
I also tried to mount it in an aluminium box, but with the circuit mounted about 3 mm the power dropped even more.

All tips are appreciated, including the "That transmitter sucks, and you should build *this* one instead" tip! =)

/Anders

My question to you would be "How are you measuring the output power?".
Measuring the input current doesn't necessarily give you the output
power.

There is nothing inherently wrong with the circuit. The two output
transistors
are wired as an astable multivibrator. The coil and capacitor connected
across
the collectors controlls the frequency at which it oscillates. If one of
the
transistors, T3 or T4, were bad, it wouldn't put out anything at all, so
they
are both operational. This circuit also runs those output transistors
very hard
and they are putting out the most that they can. The only thing that I
can
see that would account for a loss in power would be the coupling to the
antenna. If you are not properly matched, you are going to loose a lot
of
power.

You might be able to increase the power by getting some higher powered
transistors. If I remember correctly the 2N3553 is a 5 Watt device.
However,
at those frequencies I would derate it to probably half that, or more.
I use that same transistor in a QRP transmitter. On 80 meters I can
get about 2 watts RMS out of the transistor. However, as I go up in

frequency
the power starts to drop. On 15 Meters I can only squeeze out about 1.2
Watts.
You are running much higher than that so I would say you are getting
about
all you are going to get.

Also, if your circuit is built like the drawings you will probably
experience
a change in the output, due to near by objects. Most of the problem is
that
there is not a good ground plane to work against. Mounting in a
aluminum
box is a good idea but you will have to re-adjust the output frequency
and the
antenna coupling when you do.

Source record: 53103

For some reason, I really don't want to purchase a dual band mobile or base radio with cross band capabilities (guess I'm just cheap) so I have thought of several ideas and would like to hear some input on either the technical or legal aspects of these ideas:

1. Use two "wireless" intercomm systems. The type that plug into the wall. Correct me if I am wrong but I believe some of these use a carrier current type of system to talk back and forth to eachother. Of course I would have to modify one or both with either a VOX or CTCSS operated relay to key the transmitter at the base side. That might be a pain......

2. Use my VX-5, Alinco DJ-C4 and an FM Broadcast band transmitter. The FM transmitter would transmit the recieved audio while the alinco serves as the reciever to carry my transmitted audio from the VX-5 to my base station rig. I could probably do some crazy split VFO operation on the VX-5 to listen on 88-108MHz and transmit on 70cm somewhere. The VX-5 would be setup to transmit a CTCSS tone which would be recieved by the alinco and would then activate a tone decoder and relay.
The only things I find iffy about this setup, or either of them, is the re-transmitting of ham radio transmissions (forgot the rule on that...) and the presence of RF feedback or reciever overload from my 2m transmitter (about 35 watts).

Any ideas, suggestions, precautions, legal advice? Do I have some good ideas or not? Any help is appreciated and welcomed. Thanks and 73!!

Yikes, that's a very simple power oscillator circuit. I suspect it's not terribly stable and the output power and frequency will vary pretty considerably with respect to the load. I also suspect it's not particularly clean.

Generally speaking, you want the frequency determining oscillator to operate with a light load, and you want at least a couple of stages of amplification between the oscillator and the power amplifier to isolate the oscillator from variations in frequency and power induced by changing load. This circuit fails to take into account this general wisdom. Further, the spectral purity of the output signal may be poor.

Martin gives good advice, but I'd suggest that this circuit is not suitable as anything except a laboratory curiousity. If you're interested in low-power FM broadcast, alt.radio.pirate tends to be a pretty good resource. Since I'm not familiar with the legal issues of LPFM in Sweden where you seem to be posting from, I won't comment on any potential pitfalls you might encounter there.

Good luck,
Dana

2609. ?RF-Proofing Supplies?

I have a problem where my attic mounted verticle for 2m (a Cushcraft AR-2) interferes with one of the television sets in my house. Since every bit of cable for TV in my house runs through my attic (CATV and DSS) I want to try and RF-proof these cables. I have heard of wrapping toroid cores around the cable but have some questions about that, snap on toroids, and high pass filters.

Regular toroids, is it a good idea to wrap coax around these for getting rid of interference and if so, what type of material should I be buying? For the snap on kind, are the ones radio shack sells decent? I am looking at a snap on one and one of the split type that you have to wrap the wires around. Are these any good? Where can I get toroids, basically? Palomar engineers sells a kit if I remember.......

High pass filters, I have some of those from Radio Shack. They don't seem to do much except for stop one TV from loosing all its color. Are there any better ones out there? In my attic I have a diplexer for running a TV antenna and a Satellite on the same cable. Should I put the high pass filters on the ins/outs of the diplexer or should I leave the satellite cable alone? I also have CATV up there. It runs to a splitter that takes it to two separate places in the house. Where, if any, should I put high pass filters on there?

I will be using my attic for most of my hamming. I live in a restricted area and actually my antenna mountings are not bad, except for all the interference I cause. Any suggestions are welcome and I thank you for your time and patience. 73 all!!!

PB.

Hi Bill,

This whole thread has probably gotten a bit out of hand...maybe I over-reacted initially, but it seemed like the original poster was condoning "TRANSMITTING" DSB to provide 2 signals at the other end, with the other station listening to whichever ONE sideband was least interferred with. Just sounded like "I don't care how wide my signal is, as long as my buddy at the other end can hear me" syndrome...the hell with anybody else trying to use the band.

I, like you, prefer to narrow up my signal as much as possible to be a good neighbor. With today's rigs with things such as narrow IF filters, IF Shift, etc., there seems to be a better way than modifying a radio to transmit DSB.

No new math??? Darn, I just learned it the other day ;) Guess I have to forget about that!!!

Not only do they have 602's, but they have 612's as well (a slightly cheaper version of the same part). They have the added advantage of very attractive shipping for small dollar-value orders.

But like Pete says, it's an awful useful chip so it's worth ordering a bunch.

PB

The first question I would ask is, are you sure you are getting into the wiring? Most modern consumer electronic equipment is built very cheaply and is subject to overload. 2 meters is right up there between the TV channels, so if you are running any amount of power at all, it could be a problem. Your antenna is non-directional, so if it's close to the problem TV, is may be just getting in through the case. Dollars to donuts the case offers no shielding. Another good possibility is on the power wiring.

2 meters is especially problematic because if it is getting in on the cable, you need a notch filter. A high pass filter, which is a common fix for HF TVI, isn't going to touch your 2 meter signal unless it has a cutoff above 2 meters, in which case it's going to do a better job of eliminating channels 2-6 than eliminating the 2 meters. A low pass filter will whack out channels 7 and up.

If you have a problem on a few channels that are spaced widely apart, or just one channel, it is possible that a filter on the transmitter could help. But if it affects all channels, or a bunch of channels close together, then it's probably an overload situation and somehow you will need to reduce the RF getting into the set, which can be a real challenge. The Handbook has a nice chart of the relationship between the TV channels and the ham band harmonics that can be handy.

The main thing toroids do is help keep stuff from following the shield, or the power wiring. It may be worth putting a few on the power wiring right at the TV and see if it does any good at all. You want to wrap the wire a few times through those snap-on ones. And it doesn't hurt to use a few of them. But they want to be as close to the set as possible.

Nothing wrong with the Radio Shack toroids except that they are so expensive. When you are working this sort of problem you end up needing a whole pile of them. A while back I got some cheap at MECI, and I think I saw them at BG Micro cheap more recently.

Hope this helps

> interferes with one of the television sets in my house.

What is a "verticle ?" I will assume it is what we call a vertical in English. Best mounted outside, but sometimes you have no choice.

Anyway, besides that, if it is only interfering with one TV and not others, it might be you need to do something to that TV. Maybe it has a VCR in line with a horrible wideband amplifier ? If so, you are stuck. Otherwise, a simple filter at the TV input might do. Even a 1/4 wave stub tuned to the 2m band.

A really small 5/8 vertical whip on the gutter will hardly be visible and might be a much better performer and cause less TVI than anything in the loft.

I recently came by a Johnson KW Matchbox as part of a package amplifier deal. The device tunes perfectly, but the SWR/power meter didn't work. Upon pulling the cabinet apart, I found that the meter and all of its supporting components are in a sealed can, and that the shielded cable was cut.

I would like to get the meter working again. It seems to be in good shape, and still has free movement, but the original documentation doesn't say much about where to hook it up. If anyone can give me some guidance on where to reattach these wires, I would greatly appreciate it.

Thanks!

73,

If I remember correctly ...

The shielded can should have three wires attaching to "tip jacks" at the
rear of the chassis, red black and white. These
"tip jacks" are used to connect a Johnson SWR-coupler that sits in the
coax
line to the meter which is switched forward and reverse.

Regards,
Ed, N5EI

Go to LB Cebik's website for a schematic of the tuner.

http://www.cebik.com

You will have to provide an external directional coupler since the tuner itself contains only the metering circuit for such a device. Frankly, I would not bother with it, but rather would use a more convenient external SWR meter in the coax to the transmitter.

Hi Richard - except for a few "entry level rigs" all modern and most older ones as well have an RF gain control. A favorite operating technique for DXers and CW ops is to turn RF Gain down somewhat and AF Gain up, and using headphones, allows for much easier copy. Would NOT own a rig without RF Gain myself.

Most amateur gear nowadays merely unbalance the balanced modulator
and bypass the filtering to produce lowlevel AM (DSB with carrier)..
sounds like your radio is NOT doing what is it supposed to be..
actually if you could run SSB-RC (singlesideband with Reduced carrier)
you could be still copied by AM stations with no problem..

Mark,

You didn't say what kind of antenna you are using. A vertical, or longwire with a poor ground can cause this problem. You can try to load them all day but you will never get full output without damaging them! If you need a ground either install one or use a ground tuner.

2629. SV: Help needed: Too low output power

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-27 22:24:30 UTC
From: Anders <anders.gavner@removethis.swipnet.se>
Message-ID: <kjmG6.1563$vR1.5905@nntpserver.swip.net>
Source record: 53125

Thank you for all your answers!

First, the output power measuring is done by a combined SWR/Power meter. I have also compared the heat from a 75 ohm resistor (dummy load) when connected to 13,6 vdc source and when connected to the RF output. The difference in heat is remarkable. The first is burning hot and the other is just tepid. Conclusion: My transmitter doesn't output 3W!

Dana: I'm aware of that the spectral purity is questionable. Therefore I have connected a chebychev low pass filter to the output. However, I am not planning to be a radio pirate. It is just for fun, and for the feeling of "I have built a transmitter that reachs to a friend of mine who lives 10 kms from me". That's enough for an electronics geek like me.

Finally, could the lack of ground plane be of significance as suggested by Martin?

More tips of better designs are most welcome!

/Anders

Actually you will probably spend less money by buying a commercial tuner, used, at a hamfest. The components for a 100 watt tuner can be had but are often very expensive, while dozens of Drakes, Kenwoods, and even the venerable old Johnson Viking Matchboxes are sitting on display tables for 50 to 200 bucks! I bought my Matchbox, a 275 watt unit about 5 years ago for under 100 dollars. My Drake MN2700, a 275 watt tuner was about 125 dollars and the most expensive of the lot, the Kenwood AT230, bought because it matched a radio was 250 dollars, but it was in pristine condition. I know it sounds like a bad idea, but check ebay!

Except the RF gain control is almost never a RF gain control.

It is almost always an IF gain control, or at very best a mix between
IF and RF is some rigs.

The name often isn't what it really is.

I have several 16 channel Maxtrac mobile radios for sale Model number D34MJA7DA5CK. These radios came from a city Police Department and were all working when taken out of service less than 6 months ago. They come with power cord and microphone. These radios program in the 439 to 470 range. I would rate them at 8 1/2 out of 10. For and extra $10.00 I will throw in an external speaker. I accept Paypal or money orders. Again radio, microphone and power cord $115.00 each.

Aye, and there's a drawback from that... A true RF attenuator,
preferably a passive switched resistor attenuator would help the units
performance against overload and such. It would cut down the interfering
signal BEFORE it reached any active stage.

Manufacturers tend not to offer that type though, it takes more parts and
adds cost to the radio. Hmmm... I wonder how hard it'd be to hack into
my radio and add one....

What kind of amateur equipment?

Most shortwave amateur gear *does* have a RF Gain control.

VHF/UHF gear usually doesn't. Years ago, I'd say this was because there
wasn't enough RF floating around on VHF/UHF to worry about front-end
overload. (the primary reason to have a RF Gain control)

Today, front-end overload at VHF/UHF *is* a significant problem for amateurs
- but we still don't have RF gain controls. My guess is that the radios are
so small there simply isn't enough room for another knob!

In another life I used to be a repair/calibration engineer, and can tell you the only way to check any instruments calibration, is to have it checked by a specialist calibration company, who use traceable accuracy equipment which itself is calibrated on a regular basis to national standards (UK) you cannot get more accurate that that!

If you only want to know the accuracy i.e. if still in spec? and not have them actually re-calibrate? it will cost a lot less, ask for an error check only price.

Industry have to have all equipment check every 3 months or so? very expensive but necessary, apart for cleaning a cal check and certification rarely need actual adjustment.

If you are a home user and only use it for trouble shooting and monitoring? as others have said if it has not been tweeked and you have no reason to doubt it's accuracy? leave well alone, as you may well upset what is probable a reasonably accurate scope as it is.

Most scopes have good long term stability and when warmer-up (30 mins) are more than good enough for home use, only needing re-calibrating after repair. It is probably more accurate that anything you have at home to check it against.

Hope this helps Doug

>me why the difference?

Practically all AM/SSB receivers have automatic gain control (a.g.c.)
in order to produce a constant IF voltage to the detector (which is
very important when a diode envelope detector is used for AM
reception) and thus produce a constant audio level regardless of RF
signal strength.

The a.g.c control voltage is derived from the demodulated audio or
from the IF signal after the narrow band (2/3/9 kHz) filter but before
the detector. This control voltage is used to control the gain of the
IF stages and in some cases the RF gain prior to the first mixer.

This works very well, when there is only a single signal (the desired
signal) coming from the antenna.

In the real world, there is a large number of signal coming from the
antenna, some of them much stronger than the desired signal. In an
ideal world, these strong signal are amplified by the first stages but
then filtered out by the narrow IF filter and only the desired signal
will reach the detector at constant amplitude due to a.g.c.

However, in real world, the strong out of band signals can be
amplified so much that they will overload the mixer or some IF stage
prior to the IF filter, creating all kind of spurious
(intermodulation) products, masking out a weak desired signal. The
mixer is especially prone to generate such spurious signals when
overloaded. Typically increasing the signal level by 10 dB will
increase the spurious signals with 30 dB !!

In portable rigs, in which power consumption is a critical, it is very
hard to build mixers that do not overload.

For this reason, it is generally a good idea to minimise the gain
prior to the narrow IF filter. Amateur transceivers typically have a
low gain preamplifier (if any) in front of a strong SBL-1 style diode
ring mixer with attenuation. On CB, too much RF gain is often used and
weak active NE-602 style mixers are used, generating much more
spurious signals.

In a single signal environment, the RF gain could be set to maximum,
but with strong out of band signals the spurious signals would swamp

the weak signals. Reducing the RF gain by 6 dB will drop the desired signal by 6 dB, but the spurious levels will drop by 18 dB, thus the signal-to-spurious ratio will increase by 12 dB. By adjusting (dropping) the RF gain the spurious signals can be attenuated sufficiently before the desired signal drops into noise.

On high quality receivers the amplitude of out of band signals can be so much higher before spurious signals are generated that an RF control is not required.

Most of the mid to high range amateur receivers have exactly that - a switched resistive attenuator in addition the RF gain control (which generally acts on the AGC circuit). Some even have a means to switch the RF preamp in or out or alter its gain in a couple of steps.

Most recent Icom VHF and UHF rigs have an RF gain control. The squelch control acts as an RF gain control as well as a squelch. At least this is true of the 2100H and 2800H. This is not true of older rigs, tho. On the 706, the RF gain control works at VHF for CW, RTTY and SSB modes and as a squelch on FM/AM.

I would argue that it takes a lot of parts to implement an RF gain in the RF ... in most modern rigs, the RF gain is merely an input to one of the microprocessors, which in turn controls all the amplifiers. Making it work at RF rather than IF is simply a matter of ones and zeroes. This is true of the relatively complex 706MkII, as well as the very simple K1.

Just as easy to switch to the opposite sideband, or simply QSY two kHz...
Rather convoluted means to
solve an otherwise simple problem.

A lot of variables at work here. Did he sell an etched board for this
project?

Emitter lead lengths are critical, operating voltage will make a large
difference, and the coil dimensions are also important. If you simply
breadboarded the circuit, that could be a large portion of you problems.

- I etched the board myself. I did not buy it.
- Operating voltage is limited by the 18 VCeo limit in the power transistors, I have already screwed one.
- What do you mean by "simply breadboarded"? Do you mean that it isn't built on a RF board with a ground plane?

Finally, is the circuit on the link below of better design, or rather, should I build it instead?

http://www.aaroncake.net/circuits/3Wfmtran.htm

many thanks

Because most modern amateur rigs do not have an active rf stage--or, at least one that is easily made to be 'variable'. Nor, do they need under most conditions. My vintage SX-28 receivers have RF gain controls, But then again they cascade up to two RF amplifiers at the higher frequencies to achieve reasonable image rejection being single conversion designs.

What kind of 75 ohm resistor? Most of higher-powered resistors
are wire-wound, you have to be careful to get a carbon-composition
resistor, or, this might be a little contentious, even a metal-film resistor.

A wirewound resistor will be quite inductive at VHF frequencies
and act like a low-Q inductor rather than resistive dummy load and
make it impossible to get useful power readings.

The ARRL publishes some interested low-power (QRP) projects,
including power meters, that may be useful as background information
to you.

> Dana: I'm aware of that the spectral purity is questionable. Therefore I

Given the configuration of this "power oscillator" transmitter, I wouldn't
be surprised if the low-pass filter is perturbing the frequency and power
characteristics of the transmitter.

Some hams use a "dead bug" construction style where the parts are simply assembled on a piece of double-side PC board with etchings.

Your success in etching a board depends on whether the original design relied on a large copper ground-plane on the backside of the board, the frequency and placement of the thru-hole grounding points, etc., and to some degree the board thickness and dialectric. At VHF frequencies, any stray inductances, especially in the emitter leads which will be degenerative, may give you power problems. The original schematic did show 12-volts as being the power the source, but I wouldn't be surprised if the builder actually used a more standard 13.8 source during testing. You are also at his mercy regarding power output claims--what did he use for a meter? Did he include harmonic filtering? Directional coupler in-line SWR/power meters are often much more sensitive at higher frequencies, so harmonic energy may have influenced his claimed results. You just don't know, since the design basically relies on the word and skills of the original builder, with no peer review before publication.

There are no easy answers to your questions.

Regards

Peter

2649. 17 Meter DSB rig - progress report

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-28 16:12:02 UTC
From: n2cqr@clix.pt
Message-ID: <3aeae9d9.18127337@news.clix.pt>
Source record: 53138

I stopped off at a hardware store yesterday and bought some super glue. This morning I used it to build the first stage of the 17 meter DSB rig: the Variable Crystal Oscillator. I used the circuit from Doug DeMaw's "Barebones superhet" (June 82 QST) Very simple. I used a MPF102 instead of the 40673. The stage went together very quickly - Manhattan style is the way to go! I'd been listening to 17 meter SSB as I worked. It was very satisfying when, at the end of the morning, I connected a 12 volt battery to the circuit board and heard my new oscillator through the receiver. I got very good "swing" in the crystal -- -lloks like > 20 Khz.

I think I'll build a direct conversion RX to go with this rig -- this way I'll be listening to both sidebands at the same time and will be better able to avoid interfering with nearby stations.

Find a plastic or paper tube or fab one the same diameter as the ferrite rod, wind about 20 turns of small gauge wire on the paper/plastic tube, measure its inductance or find it's resonance with a known capacitor and a GDO. record same and caculate the value of L from 1/2 pi sqr(lc). The wind the same coil on the ferrite core and note Its inductance increase by the privious tests. This will give you the Al of the core and from tables in the ARRL handbook you wil find the core type by mix number. Good Luck, Bob, KE6F

What kind of 75 ohm resistor are you using? IME, most low value
resistors are wire-wound, giving significant inductance when operating
on high freq., and throws your measurements off. For my dummys, I like
to parallel many high-value small-power resistors.

The Handbook I have only has information for toroids, not rods, and you can't apply toroid data directly to a rod. When you wind a coil on a ferrite rod, there's a huge air gap in the magnetic path, from one end of the rod to the other. (If not for this, it couldn't function as an antenna.) The air path has a very large effect on the characteristics of the inductor, one of the most notable being a dramatic reduction in the Al value from what you'd get from a toroid of comparable dimensions. The amount of reduction depends on the length/diameter ratio of the rod. Another effect is that the inductance becomes relatively insensitive to the permeability of the material itself. For example, for a rod length/diameter ratio of 10, the effective permeability of a rod with material permeability of 100 is 40. Increasing the material permeability to 1000 increases the effective permeability only to 60, and material permeability of 5000 results in effective permeability of about 70. So it can be hard to tell one rod material from another by a simple inductance measurement. It might be possible, though, depending on how carefully you can make measurements, the length/diameter ratio of the rod, and what types of material you're trying to distinguish between. Go to http://fair-rite.com, select Catalog, then go to page 139 for a graph of relative permeability vs length/diameter ratio for several materials.

There seem to be a couple of mistakes in the schematic. For one, you have B+ connected to ground in the bottom center of the schematic. For another, the diode is in backwards. With the direction shown, increasing RF output will drive the audio amp cathode negative, causing increased audio, causing increased RF output, etc, etc, a vicious circle.

2657. MOSFET output impedance

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-29 03:52:58 UTC
From: Bojangle Chicken <bojanglechicken@yahoo.com>
Message-ID: <9cg7fteet1@dipsy.missouri.edu>
Source record: 53052

Simple question...

I'm working with a self-designed rf amplifier using an irf530 power mosfet. I've got the amplifier biased and working, sort of. My question is in regards to measuring the output impedance so that I can match the load to the amplifier.

Basically, I was sitting there at the bench thinking of how to model the mosfet using ac analysis when it suddenly hit me that I was wasting my time [I think...that's the root of my question-to-come]. What I did was to replace the load with discrete resistors from about 500 ohms down to about 12 ohms, measure the rms voltage, and then compute the power (Vrms^2/R). I got a peak power around 82 ohms with a dc-blocking capacitor of 1nF...therefore, I have the real part of the load. Correct? Also, I tried several different sizes of capacitor, and 1nF produced the larges rms voltage.

Am I correct in assuming that the [very approximate] output impedance of the amplifier is Z = 82 - j10^9/w ohms? I'm essentially using basic concepts for equal power transfer, but with imaginary components as well. Is there any better way of getting a rough estimate for the output impedance?

Thanks for the help.
Pete

Hi Pete,

It is not clear if you modelled or played with the actual part.
Also, I am not sure if you want to build a power amplifier, or just a small signal amplifier. What class? What frequency?

Output impedance of the transistor is not of great importance in a power amplifier. You may want to compensate for the reactive components, but the real part has nothing to do with what the device sees from the load. Whether you simulated the PA (it is interesting though if you have the right model) or you just played with it on the bench, the so called optimum load resistor, for peak output power, varies with the device gain, power supply and drive level. The point is that complex conjugated impedances theory does not apply in PA matching. The concept is different. You may want to go to the Motorola (or ON Semiconductors) or Philips web site and read some app notes about how to design a RF PA.

Good luck,
Cirip

The triode is an inverter stage. For a fixed grid voltage, the cathode
going more negative will cause more plate current. That causes the
voltage on the plate to go down (inversion). Assuming the coupling
cap passes the change, this makes G3 voltage drop also. This in
turn reduces the amount of RF that reaches the plate of the pentagrid
tube, where the diode detector is sampling. This decrease is seen
by the cathode going less negative. Thus a negative feedback loop.

Why do you want to know the output (internal) impedance of the transistor? What will you do with that information if you ever get to know it ?

The external load on the transistor is simply calculated from the peak voltage across the transistor and the peak current (supplied by the transistor) flowing through it. R = V / I.

Nothing at all! The output matching network for a power transistor is designed according to the manufacturer's datasheet information about the load that need to be PRESENTED TO the transistor - in other words, the load impedance that the transistor "wants to see".

A few year ago, an applications engineer explained on this newsgroup how the optimum load impedance is determined. It is a compromise between several different factors, including: maximum voltage rating, maximum current rating, power output, power dissipation, power gain and (if relevant) linearity. The engineer uses a variable tuner to explore the effects of load impedance on all of these characteristics, and comes up with a recommendation that balances all the different factors involved.

You could do exactly the same, given the equipment, but you would almost certainly come up with a different optimum load impedance, reflecting your own judgement about your own set of priorities.

The internal impedance of the device is irrelevant to any of that, and you don't need to know it.

One point to check is that some device manufacturers specify the actual load impedance, while others specify its conjugate - but that still is not the internal impedance of the device.

Let me add to Ian's summary that a long-used rule of thumb for HF amplifiers is (Vcc^2)/(2*Po) where Po is the output power in watts. If the transistor is driven to saturation and has appreciable Vce(sat), then Vcc-Vce(sat) is often substituted for Vcc in the formula.

You'll find this formula used in Hayward & DeMaw's _Solid State Design for the Radio Amateur_ (ARRL) -- which you definitely should get if you don't already have a copy -- and other publications dealing with RF power amplifiers, such as Motorola's app note AN721, "Impedance Matching Networks Applied to RF Power Transistors".

The constant "2" in the 2*Po part of the above formula is usual for
class C operation. The ARRL Handbook, using "K" in place of the "2"
says:

"K = a constant that approximates the RMS current to dc current ratio
appropriate for each class (of operation). For the different classes
of operation:

Class A, K = 1.3
Class AB, K = 1.5 --- 1.7
Class B, K = 1.57 --- 1.8
Class C, K = 2 "

> transistor? What will you do with that information if you ever get
> to know it ?

It is not the impedance of the transistor that I care about. It's the impedance of the amplifier that matters to me. I'd like to be able to get a match to it. If the amplifier impedance is 10 ohms and I go sticking a 1kohm resistor across the output, I'm definitely *not* going to get optimum power out.

> The external load on the transistor is simply calculated from the
> peak voltage across the transistor and the peak current (supplied
> by the transistor) flowing through it. R = V / I.

This is pretty much what I did. However, I did not have any books with me at the lab, nor do I have many at my present location (most of them are 2 hours away), so I was just looking at a quick-n-dirty method of finding the approximate impedance that I need the load to be to get near-maximum power out--i.e. I want to get as much of the rf current into the load as I can. I will not using transformers to match the load.

Thanks for the approximations Roy, Ian and Wes.

Hi, Everybody,

One of the cells in my wet nicad backup battery in my shack went to zero volts and I couldn't revive it. I had nothing to lose, so today I flushed out all the electrolyte (and debris) and now need to replace it. Then I'll try recharging it. What should I use? I don't even know if the solution was an acid or a base, and an Internet search turned up nothing for me.

For the record, it is an Alcad DLP-6 cell, around 100 A-h or so.

Thanks for any help you can give me.

Regards,

Al W6LX

Please do reply to (leeassoc@hotmail.com)

At this site:
http://www.aaroncake.net/circuits/3Wfmtran.htm

looks like I've got everything but I need the "parts" that makes it more superior or powerfull up to 5wat.

I am not sure which of this list below would be the one to change for the better to make my fm trans. go beyond 1 mile.

I have a veronica 1w without antenna and had it for years where now looks like the little light is out, and I have to hold it in my hand to even work or add something metallic to it, the 2nd board I have is broken and all it does is change the stations. That seems to be missing one metalic tube on it...

Thanks..

Thanks to Wes for a good formula explanation, but doesn't a device
have lower impedance on input and output when frequency approaches
maximum freqency, or is it just caused by the fact that voltage swing
and gain is lower?

Thanks for the reply Bruce,

Alot of design plans I've looked over were form QST mags and also different books I've found at the library. I've also spent many hrs on the net doing research as well.

Others have replied about using copper strips and apparently the one major difference is that it increases the efficiency (which modeling also shows) by reducing the "radiation resistance". The downside is that it produces a narrower band width. Other than that the circumference etc. remains the same other than construction of the support mechanism.

For construction purposes I'll be mounting the Cap on top with the drive and coupling. I wasn't sure why there was 2 styles of coupling for loops that's why I was asking. Nothing I had read indicated any reasoning for either of them.

Other than that I have a couple more item to get then construction finally begins (only been two yrs or more since I started looking into a HF antenna... what's awhile longer)

73,
Tony

The formula that Roy first presented and I expanded on computes an
optimum resistive, i.e. non-reactive value for the output load
resistance. In an r-f (or any AC) situation, it normally assumes that
the reactive parts are dealt with by some type of tuning so that the
net reactance is zero.

The formula does not address the input at all, nor does it address the
gain of the device. It simply calculates the value that delivers the
required power output.

In other words, if (sometimes a big if) you can drive the device hard
enough to cause the peak-peak voltage swing to occur at the drain,
collector or anode, then with the calculated load resistance you will
achieve design power output.

To clarify further, this value is the resistance that needs to be
presented to the device output terminal. It is not the resistance
that is presented by the terminal to the outside world.

Bill: It is a style currently very popular with QRP homebrewers.
You start out with a copper clad board and some scrap copper clad
board. With the scrap, you cut out small "islolation pads" and crazy
glue them to the copper clad board (to the copper). These pads are
used for those junctions that are not at ground. All the ground
connections go to the board. Circuits go together VERY quuickly and
this style makes circuit modification and experimentation very easy.
It is called Manhattan becasue when you look down on the finished
product, you see a pattern that looks like the street pattern of
Manhatan island.

Just out of curiosity, you don't happen to have the AutoTuner button turned on do you? The built in tuner (if you have it installed) doesn't work on 160 and if you have it "on" you can get low output power. Been there, done that on my 690S. Just a thought.

I am posting here because of some of the nasty things I have read in this group and in QRZ discussions regarding freebanders. We who use the frequencies from 27.405 to 28.000 have more in common with hams than you might think. We are good operators and have knowledge of propagation and skip conditions. We use Yasus, Kenwoods and Icomm radios just like you do, so we know technical issues as well or better. However, the attitude of some hams toward us is rude and condescending. We are treated like 2nd class citizens. This should not be. We have the same rights under the constitution as legal hams do. For those that do not wish to be under Uncle Sam's thumb, freebanding is a viable alternative to getting a ham radio license. What I am saying is that maybe the next time you meet a freebander it might be wise to talk with him before you condemn him.

I am QRT and standing by. (No flames answered. Please reply via email)

2687. Re: MOSFET output impedance

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-04-30 21:20:47 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3AEDD72F.C687848@eznec.com>
Source record: 53084

I'd like to add that the formula is generally used only at HF and below,
where the transistor's ft is typically much higher than the operating
frequency. At VHF and above, the transistor's S parameters are usually
used for designing input and output networks.

Roy Lewallen, W7EL

The Constitution doesn't grant the privilege to transmit...the FCC
does. If the free-banders are as 'good' as the hams, then there
should be no problem to get a license and enjoy even more
privileges. Getting a license these days is like a walk in the
park.

Answer to my own query, in hopes it will help others:

Alcad has several distributors in the US. Call 203 234 8333 and they will tell you who is the closest distributor. In southern California, that would be Partridge & Associates, 562 802 7345, in Cerritos.

The electrolyte normally never needs to be changed, but over time it may react with the carbon dioxide in the air and the resulting carbonate contamination can weaken the electrolyte and require replacement. I never knew this.

You can buy pre-mixed potassium hydroxide (KOH) electrolyte, in five-gallon jugs, for $50 each. That's enough for roughly 20 cells of the 130 A-h size. The beauty of Nicads is that structurally they will last forever because there's no mechanism for corrosion of the plate structure. With a fresh load of electrolyte, I should have my cell back to normal.

I had to do this with the impending power shortage in California this summer!

R,

Al

I don't see what this poor guy did to incur the wrath you're showering him with. He's pleading the rights of honest law abiding CB'ers. There are such people.

You chose to become a ham because you wanted a little more, and you were able and willing to go an extra step to get what you wanted. He chose to invoke a basic legal privilege that gives him the satisfaction he wants. Everybody should be satisfied that they got what they needed in this arrangement, but that's not good enough for you. You have to prove your own self-worth by dragging him through the mud.

I've been a ham for over 35 years, and I'm proud of that. Most of the people I've met in this hobby are intelligent, thoughtful & tolerant. I'm proud to know them. There is, however, a small but vocal redneck element that makes me feel like the stereotype social-misfit propeller-head nerd that many people think hams are. You, my friend, fall in the latter group.

I'm not too proud that you're one of my hobby peers.

Yes, and he's not one of them. Read the subject line. "Freeband"
refers to the area between 10 and 11 meters unallocated to either
service.

If only things were as simple as black and white...

Do the airwaves care if you transmit on 14,040MHz or 150,015MHz? Of course they don't. What about lightning? It transmits on all frequencies? Let's start a petition to legally limit lightning transmission...

This is 100% ridiculous. Why are people getting worked up over something that someone else is doing that has no bearing on their lives? Does it really matter if Joe Schmoe is transmitting on 27,405MHz with 20kW? As long as it doesn't interfere with your signal, it's none of your business.

By the same token, does it matter what we hams think of Twisthed's kind? Of course not. Unless we're willing to do something about it. Since that's not the case, enough already.

This was fun.

Certainly, you have the same rights as licensed hams.

Those rights do not include the right to transmit in 27.405-28.0. (neither you nor I have that right) Legal means exist for you to carry out the type of communications you're carrying out in that band. Indeed, the legal means that exist use exactly the same type of equipment you're using, and the expense involved in getting a legal license is miniscule.

A very iffy case can be made to suggest the broadcasting service regulations infringe on free speech rights. None of those arguments hold any water with regard to amateur-type communications, which are accessible to any American at reasonable cost.

Understand also, that your type of communications is causing significant problems for licensed hams. Firstly, because not all freebanders are technically qualified - and those with no interest in the radio hobbies can't tell the difference between a freebander and a licensed ham. Us hams are blamed for the interference caused by poorly-designed amplifiers used by unqualified freebanders.

Secondly, because not all freebanders stay below 28MHz. The ones that find their way into our band are causing SEVERE interference. Those operators are most assuredly not welcome.

>For those that do not wish to be under Uncle Sam's thumb, freebanding is
>a viable alternative to getting a ham radio license. What I am saying is
>that maybe the next time you meet a freebander it might be wise to talk with

Actually, this much is true. The first part, unfortunately. The second part, because it is not at all impossible to "reform" freebanders. It will probably become easier as the sunspot cycle declines and the 10.5-meter band becomes less and less useful.

Personally, I don't get bent too horribly far out of shape over freebanding, PROVIDED that they stay below 28MHz. Those who find their way above the border are welcome to the full wrath of the FCC.

2703. Re: MOSFET output impedance

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-01 04:57:19 UTC
From: Bojangle Chicken <bojanglechicken@yahoo.com>
Message-ID: <9clg08$1e6$2@dipsy.missouri.edu>
Source record: 52998

S-parameters are something that I'm going to become familiar with in the very near future...I can almost 'see' it.

By the way, using the method that I originally described (the ki0eg method) I obtained about 80 ohms resistive. According to the calculations, this is about right. Also, measuring the voltage (rms) transfer, I found the output to be related to the input by a factor of 5.1. For the entire measured range, the Vout/Vin plot was a straight line (very straight). I made the assumption (I know it's not realistic) that the voltage transfer worked at any voltage, which allowed me to calculate an output power of 20W. I've got a 10W 80ohm load that gets unbearably hot dissipating the output signal, so I'm quite sure that I'm getting more than 10W, but probably less than 20W.

The point of all this is that when I decreased the load resistance by a factor of 2 (i.e. Rload = 40ohms) I got an increase in output power that roughly corresponds to somewhere between Class AB and Class B using the Rload = Vdd^2/(kPo), where k is variable between 1 and 2. This means that, although the formula seems to be off by a constant in my case, it's roughly correct. It's nice to see the 'theory' work out in practice (although I'd be willing to bet that this formula was found experimentally, sorta).

Thanks to those who responded. The amplifier that I came up with works just fine [as tested] into any load between 40 and 80 ohms (producing between 10 and 20 watts over the range of loads). It's really comforting to see a "design from scratch" work outright. I guess I chose the right major afterall!

Thanks.
Pete

This is a slightly unusual application, where the load can vary so widely. As previously mentioned, for an amplifier designed to work into 50 ohms you should use the device manufacturer's recommended load impedance Z_load. They also state a design value for input impedance Z_in.

Having said all that, the techniques that you'd use to design the input and output networks are pretty much the same for both S-parameters and Z_in/Z_load so you don't have to learn two different sets of skills.

I understand that part. Someone mentioned s parameters...that's just something that I'd like to be able to use. Most of my designs up to this point have demanded linearity, also, which means that s-parameters work. Do you think that the s-parameter approach would give approximately correct results, even for large-signal analysis?

> Z_in.

That's the beautiful thing...it was my design goal to have at least 10W output into a "load." When I asked what the load had to be, I was simply told "just make it output 10W" (up to 25W max). The amp is being used by a graduate student at my school for [he hopes] his thesis project, which involves ionizing a flash tube. The amp will basically be operating into an inductor, coiled around the tube. I imagine he's going to need impedance matching for proper transfer.

I will consider the thoughts presented more carefully when designing more mainstream rf systems, but approximations and good-enoughs were fine for this project. Thanks to those who replied once again.

>I don't see what this poor guy did to incur the wrath you're showering him
>with. He's pleading the rights of honest law abiding CB'ers. There are such
>people.

I respectfully disagree. This is why:

>>I am posting here because of some of the nasty things I have read in this
group and in QRZ >>discussions regarding freebanders. We who use the
frequencies from 27.405 to 28.000 have >>more in common with hams than you
might think.

The last I checked, the frequencies between 27.405mHz and 28.000mHz are
allocated to services OTHER than CB. There is no US or international allocation
known as "freeband".

While I do not argue the point that there are many "freebanders" that do
share many commonalities with Amateurs, one of them they DON'T share is
LEGALITY.

>He chose to
>invoke a basic legal privilege that gives him the satisfaction he wants.

Which "legal priviledge" was that, Joe? He can, of course, express his
opinions in USENET all day long and be completely "legal".

If he operates a "CB" radio or an Amateur Radio transmitter on the cited
frequencies, he is breaking the law.

>Everybody should be satisfied that they got what they needed in this
>arrangement, but that's not good enough for you. You have to prove your own
>self-worth by dragging him through the mud.

He did that himself, Joe, when he admitted that he's operating on
frequencies he's not licensed for.

>There is, however, a small but vocal redneck element that makes
>me feel like the stereotype social-misfit propeller-head nerd that many
>people think hams are. You, my friend, fall in the latter group.

He may have been verbose, but he's essentially correct.

I comment seperately:

>"Scott Townley" <nx7u@mindspring.com> wrote

>> But you *do* have all the respect you deserve...the same respect we
>> all grant to FELONS, which is what you are, buddy...

Not until he's convicted, but I agree with the spirit of the comment.

>> On 30 Apr 2001 21:04:39 GMT, "Twistedhed" <twistedhed@webtv.net>
>> wrote:

>>>I am posting here because of some of the nasty things I have read in this
>>>group and in QRZ discussions regarding freebanders. We who use the
>>>frequencies from 27.405 to 28.000 have more in common with hams than you
might think.
>>>We are good operators and have knowledge of propagation and skip
>>>conditions.

What you don't have is knowledge or respect for is the law. And what you
DON'T have in common with Amateurs (or CBers, for that matter...) is approval
of law to operate. And in breaking that law, you not only flaunt the
"legality" matters, you cause interference to me and others, which is
demonstration of YOUR disrespect and contempt for us.

>>>We use Yasus, Kenwoods and Icomm radios just like you do, so we know
technical
>>>issues as well or better.

Use of the equipment does NOT necessarily make you technically competent
or UNDERSTANDING of the "issues". Yes, there are some very technically
competent non-Amatuers out there just as there are some INcompetent Amateurs.
But again, just because you can spin the dial does NOT make you competent,
proficient OR legal.

>>>However, the attitude of some hams toward us is rude and condescending.

How would YOU react to someone who drives through your neighborhood with a
bad muffler and the music at 140dB...??? That's how I view Freebanders and
CBers who refuse to operate legally. If you are breaking the law, YOU expect
to be treated with teh same dignity that I would extend to a LEGAL
operator...?!?!

>>>We are treated like 2nd class citizens.

Then don't break the law.

>>>This should not be.

Sure it should.

I should respect shoplifters? They take something they did not "pay" for
too. I should respect someone who disrupts my neighborhood with loud noise and
raucous behaviour? Not likely!

>>>We have the same rights under the constitution as legal hams do.

Sure you do.

And just in case you get caught doing "your thing", the Federal Marshal who handcuffs you will remind you of them. It's called "The Miranda Warning".

>>>For those that do not wish to be under Uncle Sam's thumb, freebanding is >>>a viable alternative to getting a ham radio license.

Breaking the law is a viable alternative to complying with the law?

Hot Flash, Hot Rod, but YOU are more "under Uncle Sam's thumb" than I ever was. I have legal access to spectrum from the medium frequencies all the way through laser-length, and at power levels that in some cases exceed commercial radio stations.

The FCC's rules and regulations are NOT that restrictive nor are they that hard to follow.

Don't intentionally interfere with others. Don't use more power than is necessary to effect reliable communications. Observe the few band restrictions they require. Identify at certain intervals. Give right of way to emergency communications.

You, on the otherhand, have to be looking over your shoulder. You can't prudently give your real name of accurate address on the air lest you be directly visited by that very same Uncle Sam.

Every time you key the mike you face fines in the thousands of dollars if the FCC wanted to be really ugly about it. They can confiscate your equipment just because you have it if they find non-type accepted equipment in your possession and make YOU spend the money on lawyers to prove you are NOT operating illegally.

You do NOT have the protection of certain STATE laws that ALLOW Amateurs to have "scanners" or other radio receivers capable of receiving police frequencies in your car, and in some cases, handheld receivers.

You do NOT have the protection of certain federal laws against unreasonable construction of antenna structures from restrictive zonings.

This is fun? This is a liberating "viable alternative"...?!?!

>>>What I am saying is that maybe the next time you meet a freebander it might be wise to >>>talk with him before you condemn him.

What I can do is point out the same points I just made and suggest he cease what he is doing and "get legal" at the earliest opportunity.

And I reiterate my earlier comment: In breaking the law, ESPECIALLY wherein it involves incursion to Amatuer Radio allocations, YOU demonstrate your "condem(nation)" of Amateurs. You expect respect in return?

I think not.

>>>I am QRT and standing by. (No flames answered. Please reply via email)

No flames. Just facts.

>>>Unit 2711, Florida

What's your name? What community do you live in? A "unit" of what?

See my point...???

Spend a few hours with your nose in any one of the several dozen "license guides", get a license and "get legal". It's liberating.

Many years ago I was stuck with an old Telequipment scope whose vertical calibration was obviously way off. Not liking the Telequipments anyway, and knowing the worst that could happen was that after I tweaked it, it would still need calibration, I went in.

I forget exactly what it was I rigged up, but it was such that I did the calibration around a *ratio* of voltages rather than the absolute voltages themselves. The idea was that given three resistors in series, no matter what voltage was put across the network, the ratio of voltage drops across the resistors would always be *exactly* the same (regulated DC, 1% metal-film resistors, etc.). So I had four unknown, but *exactly* related, voltages to calibrate from. It was surprising to me how obvious the miscalibration became, and there was only one point of adjustment where the ratios showed up anywhere near correct on the scope.

When I was satisfied, I told the shop chief that I had roughed it in enough to use for work purposes. He threw a hissy fit and immediately got the scope out for recalibration, bitching about what an idiot I was to touch it, ranting, raving, etc.

When the scope came back, he didn't say anything to me; the scope just appeared in my area. When I pushed him enough, he finally admitted that my homebrew calibration method left the scope off by an officially measured 0.2%.

I maintain that with ingenuity, lots of time and patience, and willingness to try, any piece of test equipment can be home-calibrated well within the needs of the home experimenter, and danged close to factory specs. The point of lugging it in for professional calibration comes when the equipment needs (and can be expected to give) exceptional accuracy, at least for my money.

Besides, whenever any piece of gear goes away, I end up spending most of my time obsessing over when it will be back and over all the things I could be doing with that piece at any given moment. :)

I don't get it.

Seriously, Unit. Look into getting a ham license. The ham bands aren't always pretty either but having a license will certainly give you some better options...and a legitimate platform from which to gripe.

Good luck to you.

I'm using carbon coposition resistors (40 of them, at 1.6k and 0.5W apiece)
for the load. They are all in parallel. I have absolutely no doubt in my
mind that the load is not purely resistive. I'd be more surprised to find
that it didn't have stray inductance (and especially capacitance) than to
find that it did have those qualities. However, the blocking capacitor that
I used should shift the phase enough to present a nearly resistive load the
output. I basically designed the load by measuring peak power to the load
(Vrms^2/R). Once I had the load, I chose the blocking capacitor for maximum
power transfer (again). In this way, I figure I got close enough.

Generally true. While I've left the industry, I still have a few trade magazines dribbling in. I don't study them as intently as when I was working, but I have noted that there are now available computer-controlled tuners used to make high-power (relatively speaking) load pull measurements, that in conjunction with a lot of calculations can deliver "high power" s-parameters.

Maury Microwave is one company that has info on this.

The same kind of thing is available for low-level applications such as exploring noise figure contours versus the load supplied to the input.

The problem for high-level applications is that the resulting S-parameters are both frequency- and power-dependant. This presents something of a network design problem...

Well, hams use Yaesu, Kenwood and Icom (among others) so we obviously use
different equipment.

If knowing how to spell the name of the manuracturer that built your equipment
is a "technical issue" then you get an "F".

>However, the attitude of some hams toward us is
>rude and condescending.

I won't be rude and condescending, I will just look upon you with distain.

>We are treated like 2nd class citizens. This should
>not be.

You know what fella, some people *are* second-class citizens. The jails and
prisons are full of them. When they get out, they are still second-class
citizens; they can't vote, they can't legally own firearms, the military doesn't
want them, etc. Keep it up and you really can be a second-class citizen.

>We have the same rights under the constitution as legal hams do.

Certainly you have many Constitutional rights. Requiring you to be licensed in
order to use the airways doesn't infringe upon any of them.

Your (and my) beloved constitution allows the federal government to regulate
interstate commerce. While I would agree that the federal government has
stretched this authority beyond belief at times, nevertheless it has been
determined constitutional for the FCC to control the airways, whether you and
your cronies approve or not.

>For those that do not wish to be under Uncle Sam's thumb, freebanding is
>a viable alternative to getting a ham radio license.

I suppose by your reasoning that not paying your income tax is another "viable
alternative" to being under Uncle Sam's thumb too.

I think the speed limit on interstate highways should be 125 mph instead of the asinine 75 mph. I have been known to test this limit, but if I get caught, I don't believe that I'll be using any "constitutional-right-to-speed" defense as a "viable alternative" to paying the fine.

>What I am saying is
>that maybe the next time you meet a freebander it might be wise to talk with
>him before you condemn him.

Right. Next time I meet a freebander, I ask whether he's quit beating his wife since he went on the air. (Don't panic, Unit, it's a trick question. I don't have any proof that you beat your wife. You're safe for now)

> I must admit I am shocked by some of the responses to my original
> post.

Perhaps, then, you should not have posted your diatribe on a ham radio newsgroup. For the most part, Amateur Radio Operators are sticklers for communication law, and the concept of ``freebanding'', or operating in an unauthorized albeit unallocated frequency range, is an anethema.

I can understand your desire to talk DX. I can understand you enjoying the communication hobby. But why risk it? In all honesty, if certain folks (the FCC included) were to take notice of your freebanding activities, or even if you happened to operate with more than 5W out of a CB rig, they would not hesitate to track you down by your own radio signal, and drop a hefty Notice of Apparent Liability in your lap.

Is it really worth losing your entire shack, a large chunk of money, a significant number of years of your life, and your reputation just to operate?

If you really enjoy what you do, it is not that terribly difficult to get an Amateur Radio license. It took me two weeks---a week with the book, and a week with Morse Academy, to get my Tech+ license. It shouldn't take more than a month to be able to go from no license to a General (which gives you a hefty HF allocation). Another two to four weeks of study would get you your Extra, opening _everything_ available to the US Amateur to you.

If you are as courteous on the freeband as you say you are, then your operating habits should be acceptable in the Ham bands. Come on over, we'd be happy to have another courteous, well-versed op. That's not even mentioning the fun of public service events, digital modes, TV modes, microwave experimentation, homebrewing, and all the other facets that make up the hobby.

If you're really serious about communication hobbies, then PLEASE consider becoming a ham. Unless you bash the government, give out State secrets, or habitually play music or use foul language on the air, the only real difference should be the ID requirement. Considering you label yourself "RS1175", I'd say you already do that, too. The rules are simple to follow. You don't have to drop your legal CB activities, and an entire new world of communication will open up to you.

Listen to the music of the Code. :)

Good Luck,

Frank:
Motorola has a connector that you lay the fibre wire, also called tinsel wire, into a groove, that has metal pins from the bottom of the groove, you just fold the connector over the wire and crimp into the wire. There is a short piece of metal, like a wire produding, and it is this wire that you solder onto what ever you want to connect to.
Soldering to the tinsel wire is very, very, difficult and unreliable.
The Motorola Part Number "used" to be a PDK-13 Tinsel Cord Repair Kit but you should be able to buy the crimp sleeves on thier own...but not sure what the Part Number is. Maybe our Motorola Techs can help!
Hope this adds to your line of information

Well, some of what you put forth certainly has merit. I do not advocate squatting on any hammie band. I haven't listened to 10 meter in so long, so I'm not aware if the problem you allude to is so prevalent. I'm gonna take myself a listen tonight and see if hear anything. I'm not comparing hammies to cbers, YOU are. I have friends that are both. Bad operating procedures are not limited to either party. What I do see and hear all
quite oftenly, is the hammie with his modded big rig, NOT on the
freeband, but on the cb band. But you know what? We don't care. We'll talk to him just the same. This is extremely common where I reside and I live in one of the most active cb metros in the country. I've lived all over the country when I was younger and still do a great amount of traveling, and I can state without predjudice that I have heard many more hammies on freeband AND cb bands than I have heard squatters on hammie bands. Part of the problem, as you say, is the rules are wrong. Plain and simple. Not all of them mind you, but some of them. They are outdated (no dx) and make lawbreakers out of unintentional and unwitting
ops. The crux of my argument here, is that if an op is shooting DX on a frequency that a hammie is not permitted on, why the hell should that hammie give two sh*ts? If two hammies are on frequency in the 10 meter band, in the same town, each running 100 watts, (happens all the time, I can point you to a net right now where this takes place daily) what justification do you have to cry about it when 2 cbers do it on an "off" frequency other than the "I got my ticket so you should have to also"
mentality that seems to prevail among the freebanders biggest critics?

I can't say that I've ever seen discussion here about
over-powered, out-of-band equipment. I'm sure we all know
somebody with a 10kw amp, or have heard such a war-story.
Thing is, Unit, that when you have all the legal options for
different bands and a kilowatt, there's not much point in creating
some uber-illegal station because its not gonna get you any better
results than a legal one.
Shoot, I've done my share of freebanding. Ten meters as quiet as
a mouse, but 27 Mhz full of Australian and Pacific DX...but I
obviously wouldn't go down there saying I'm a ham or using my
call. I know what you're talking about. I made alot of friends
and later found out many were hams. DX is big, even SSTV is big
on the "freeband" and thats a real dis-incentive for upgrading to
getting a real license.
In four or five years from now, that part of the spectrum will
again be as dead as a stone and there's nuthin left other than the
truckers on the closest interstate to chat with...while the hams
are still working DX on the lower freqs.
Many of my best ham buddies are ex-CB types. Way back when, one
fella, who was notorious in our area for his big signal, came to
my shack with a friend. He had a complete Drake C-line, Moonraker
at 80 feet, and probably more countries confirmed than I had with
my measly boat-anchor set up. He had the same attitude about hams
as you, and I had the same attitude about 'freebanders'.
As you indicate, it was amazing we had in common. He wanted to
upgrade to something better than 27 Mhz. He had the equipment, he
had the intelligence, there was no reason NOT to upgrade himself
to become a legal operator. In the long run, he ended up whoopin
my butt on CW speed, contest scores, DXCC.

Maybe you could do the same.

You have to listen on 10m in the daytime. That's when propagation for long distance (DX) occurs. It's gone at night (usually).

==========

Hmmm... You might want to read the group's messages for awhile. I haven't seen ANY that discuss ways to make ham equipment operate out of the legal bands, or with illegal power.

In general, hams find that their LEGAL frequencies and power levels are more than enough to satisfy any urge to be able to communicate.

I used to work at a company called SBE and I did occasionally modify a CB rig up to the amateur radio frequencies. BUT with the my ham ticket that was quite legal for me to do provided that only licensed hams used the transmitter.

Please don't confuse that sort of thing with illegal frequency operation.

==========

If a "freebander" were to apply himself to a minor amount of study, get a ham ticket and then use the equipment properly than that person would earn my respect.

One that continues to operate illegally, and creates interference with the legitimate users of that frequency range tend to be viewed as a felon and worthy of fines and jail time.

I find it strange that those "freebanders" don't make the effort to get a ham license. it isn't all THAT hard to do.

Actually the people on channel six make better Hams and are more
respected than those who operate outside the CB band.

HFers....or "Freebanders"...are the bottom-feeders of the radio-world.

Sort of like the Jeep and pick-up truck drivers who go off-road, and
tear up property that isn't theirs.

Real horse's rears who don't respect what isn't theirs to ruin , if
you know what I mean.

I bet if you took a survey, you'd see most Ham's have more respect for
a "brother" who runs 20 kW on channel six than a 5 watt "Freebander"
who operates on 27.995 USB.

Personally, I think all Freebanders need to spend some quality time in
jail.

The reason is that good amateur radio operators stay within the law, and
dont advocate anyone breaking the law, ham or not.
For those hams that break the law, properly operating hams are self
policing and will try to correct the situation.
Also, people illegally operating, whether they consider themselves
cbers, hams or anything else, reflect poorly on hams, cbers, and
everyone else, in the public eye. That is why a ham cares even though it
is outside the band.

Searching for: "disdain"
Found 3 hit(s).

Disdain (Page: 423)

Dis*dain" (?; 277), n. [OE. desdain, disdein, OF. desdein,
desdaing, F. dï¿½dain, fr. the verb. See Disdain, v. t.]

1. A feeling of contempt and aversion; the regarding anything as
unworthy of or beneath one; scorn.

How my soul is moved with just disdain! Pope.

Often implying an idea of haughtiness.

Disdain and scorn ride sparkling in her eyes. Shak.

2. That which is worthy to be disdained or regarded with contempt
and aversion. [Obs.]

Most loathsome, filthy, foul, and full of vile disdain.
Spenser.

3. The state of being despised; shame. [Obs.] Shak. Syn. --
Haughtiness; scorn; contempt; arrogance; pride. See Haughtiness.

Disdain (Page: 423)

Dis*dain" (?; 277), v. t. [imp. & p. p. Disdained (?); p. pr. &
vb. n. Disdaining.] [OE. disdainen, desdainen, OF.
desdeigner, desdaigner, F. dï¿½daigner; des- (L. dis-) + daigner to
deign, fr. L. dignari to deem worthy. See Deign.]

1. To think unworthy; to deem unsuitable or unbecoming; as, to
disdain to do a mean act.

Disdaining . . . that any should bear the armor of the best
knight living. Sir P. Sidney.

2. To reject as unworthy of one's self, or as not deserving one's
notice; to look with scorn upon; to scorn, as base acts,
character, etc.

When the Philistine . . . saw Dawid, he disdained him; for he
was but a youth. 1 Sam. xvii. 42.

'T is great, 't manly to disdain disguise. Young.

Syn. -- To contemn; despise; scorn. See Contemn.

Disdain (Page: 423)

Dis*dain", v. i. To be filled with scorn; to feel contemptuous
anger; to be haughty.

And when the chief priests and scribes saw the marvels that
he did . . . they disdained. Genevan Testament (Matt.
xxi. 15).

Searching for: "distain"
Found 1 hit(s).

Distain (Page: 433)

Dis*tain" (?), v. t. [imp. & p. p. Distained (?); p. pr. & vb. n.
Distaining.] [OE. desteinen, OF. desteindre to take
away the color, F. dï¿½teindre; pref. des- (L. dis-) + F. teindre to
tinge, dye, L. tingere. See Tinge, and cf. Stain.] To tinge with a
different color from the natural or proper one; to stain; to
discolor; to sully; to tarnish; to defile; -- used chiefly in
poetry.
Distained with dirt and blood." Spenser.

[She] hath . . . distained her honorable blood. Spenser.

The worthiness of praise distains his worth. Shak.

Yours truly,

Bill Meacham

Whoa!!! The judge suspended Flippo's constitutional right to bear firearms without being convicted of any crime?

As Paul Harvey might say, "What's the rest of the story?"

2742. Re: Respect For Freebanders

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-02 15:34:22 UTC
From: twistedhed@webtv.net
Message-ID: <24384-3AF028FE-13@storefull-123.iap.bryant.webtv.net>
Source record: 53039

Three licensed amateurs:

Leland C. Scott KC8LDO AKA "Punisha of keyclowns, keyclown killa, etc.

Doug Adair N8wwm AKA: Too many to list

Glenn Sparks KI5GY AKA "Sparky"

.have been almost entirely responsible for the hate, discontent,
forges, and trouble in rec.radio.cb.

Leland has forged me for months. I exposed him last month and he has
been filled with rage ever since. I post nowhere except in
rec.radio.cb., except when a licensed hammie lets me know I am being
forged in a forum where I do ot post, then I will post one time showing
the headers. I invite all who are interested to stop in and peruse the
archives through google and see for yourselves who the troublemakers are
in our cb ng.. Watch the headers at all times. I thought leland had
slowed, but for some unknown reason, I am finding he crossposted the
above which he forged and attached my nic. He tried this in alt.ham
vhf/uhf, but a regular there saw what he was up to, emailed me, and I
posted his headers. He got no bites on his troll there so figured he
would try another ng. Note how he "Suddenly" appeared and tried to
attribute the post to me in the uhf room.. This is exactly how this all
started, by Leland forging me in rec.radio.amateur.policy, and a
licensed amateur pointed out to Leland it wasn't me but a forgerie, then
leland attacked HIM for his credibiliy. Anyone wanting these posts,
Email me. When I posted in the room showing the headers Also, almost
every post that appears to lend credibility to himself is by himself, or
Doug or Sparks, usually through ynn. mail (anonymous), home.com via
earthlink or through supernews and/or is phony..they are always phony,
even some in here, again..look at the headers. If one watches the
headers, one will see that he rapidly traverses back and forth between
mediaone (his ISP) and supernews to post when he is not forging. This is
done only for one reason..
These three waged this smear campaign against me when one of them ran
across an old article I wrote on freebanding in a magazine and posted it
to rec.radio.cb. Appears that these misguided souls can not get past the
mindset that since one writes about a subject, one must be absolutely
guilty of their subjects crimes as well. Thank you all for taking the
time to allow me to explain what took place here. Anyone wishing further
dialogue, please email me, as any other posts are forged. Have a good
day.

I am posting here because of some of the nasty things I have read in this group and in QRZ discussions regarding freebanders. We who use the frequencies from 27.405 to 28.000 have more in common with hams than you might think. We are good operators and have knowledge of propagation and skip conditions. We use Yasus, Kenwoods and Icomm radios just like you do, so we know technical issues as well or better. However, the attitude of some hams toward us is rude and condescending. We are treated like 2nd class citizens. This should not be. We have the same rights under the constitution as legal hams do. For those that do not wish to be under Uncle Sam's thumb, freebanding is a viable alternative to getting a ham radio license. What I am saying is that maybe the next time you meet a freebander it might be wise to talk with him before you condemn him.
I am QRT and standing by. (No flames answered. Please reply via email)

2743. Community Project - Thanks for the help

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-02 15:42:33 UTC
From: ZL4PY <ZL4PY@mail.com>
Message-ID: <3af02a9a@clear.net.nz>
Source record: 53040

Several months ago I had discussions here concerning a large community project analogue clock with digital temperature display for over-street mounting in a rural town. Several people here kindly came up with various technical suggestions for the temp display in particular.

Well the whole project is a finished reality now, looks great, works good and they are delighted. The mayor has been there to officially open it, everybody has taken credit for it and the local press are running a competition to prove that their town is warmer than the official statistics suggest. People bring their kids at weekends to gaze up at it in awe. (oh well ...)

I had two technical problems which may be of interest. I designed it to use electronic trasnformers to save on size, weight and heating effects. These run about 20-30Khz as opposed to 50Hz and accordingly are soft start and really small in size. On the workbench it all worked perfectly but when we installed it on site the elctronic transformers failed to light the segment lamps. We had used about 30 feet of hd data cable to switch the segments from ground level. This cable worked OK in free air but was run inside a metal conduit at the site which created an unforseen impedance problem for the electronic transformers which then remained in soft start mode and failed to switch up to full power. The problem could not be solved and we had to revert to a conventional 50Hz transformer (500VA). This meant mounting an additional waterproofed electrical box to house the transformer which in turn upset the airflow around the base of the structure and we then had to find a new temperature sensing position as the transformer core runs at 51.8 degrees C by design.

The other technical problem was I just could not get the LM335z to track linear through the full temp range so in the end tossed it and used a strapped BC548C from out of the junk box which proved accurate to half a degree C over the desired range (ratio divide by two as opposed to by ten for the LM335z)

So thanks to all those who helped with ideas. Nice one guys.

Tsk tsk, Bill. I gave you a little push to help you improve yourself by
learning a new word, and that is the best you can do. Too bad.

But you see how simple it is to learn something new. Just a tiny bit of effort
and you can achieve your goal.

Too bad "freebanders" don't put out the tiny bit of effort necessary to earn a
ham ticket. Until they do, I will continue to view their illegal activities
with distain.

It's just a guess, but I wouldn't be surprised if Bill's response was
prompted by your unique usage of a transitive verb in your comments, and
your subsequent attempt to justify it.

Does the incorrect use of a valid word make you morally superior?

- Rich

: equipment needs (and can be expected to give) exceptional accuracy, at
: least for my money.

I would certainly agree with that. I'm a somewhat serious hobbyist, and I think I could calibrate everything I own to within the factory spec, with one exception. The exception is a very nice, old, HP counter -- I doubt I could get a 1 part in 10^8 or so frequency standard that's needed to do that properly.

Going back to the 'scope for a moment. How accurately can you read voltage or time on a 'scope screen ? 1% ? (that's 1mm in 10cm). Perhaps 0.01% if you have calibrated delayed sweep or calibrated backing-off voltages (one of my Tekky's does).

Now how accurately can you calibrate a crystal oscillator, say by zero-beating it to a standard frequency transmission. A lot better than 1% I can assure you. Heck, one of those 4 pin oscillator cans will do better than that, off the shelf with no calibration (or at least every one I've ever tested bas been a lot better than 1% at normal room temperature). How accurate a bandgap voltage reference can you easily buy from, say, Maxim. Again, a lot better than 1%.

There are your standards. They're not 'traceable', but they're easily good enough for home work.

There are many advantages to being able to calibrate your own instruments, or at least being able to check the calibration. For one thing, if you mske a measurement and it's way off what you expected, you'll be able to check the insturment is telling the truth. And you won't take a whole series of measurements and then find the instrument was out of calibration and that you have to repeat them.

No, there's only one person I trust to calibrate my test gear -- me.

I don't know whether you can get S parameter data for these devices, but it's likely you can find a SPICE model. What I've done is build a SPICE model that imitates an S parameter measurement setup and use it to get the S parameters. In fact, for one microwave transistor, I found pretty bad disagreement between the SPICE-derived S parameters and the published S parameter values -- and using the SPICE-derived values gave circuit modeling results which were closer to actual performance. I'd think this would be unusual, though, since S parameters are measured pretty directly, while SPICE parameters are inferred from other measurements. I imagine that the manufacturer's S parameter test fixture was defective, improperly calibrated, or improperly used.

No amount of back-pedalling will eliminate your linguistic faux
pas, but I'll raise your grade because you were clever enough to
convert it to a worthwhile point.

Ok, Mr. Letter of the Law.

And I bet you ALWAYS obey the maximum posted speed limit. If you wanted to speed, you would take the right approach to speeding legally - because, hey man, you do EVERYTHING right. You would put your mind to becoming a race car driver and do your speeding on the track where it belongs. You would follow the proper steps to becoming a race car driver:

1. Learn to ride a unicycle, because that's how it all started, man. Our forefather's rode unicycles before fast cars were around, so must you learn.
2. Learn everything there is to know about cars - including memorizing the answers to questions about walking, unicycles, horse and carriage, boats, planes, etc.
3. If you skip the step on learning to ride a unicycle, prepare to be chastised by old-timers that had to learn how to ride it and by some who love the unicycle and can ride it at over 20 mph! BTW - learning to ride the unicycle keeps bad people from becoming race car drivers.
4. Prepare to spend some money. Your standard car won't do - it doesn't fit race car specs! And every race track requires a different car and tire combination.

Is becoming a race car driver what you should do because you like to take those 15 turns of Bear Mountain road at an faster than the posted speed? Well, ham radio IS NOT a replacement for the "freeband" either. Ham radio doesn't fit everybody. Maybe its a bit of an extreme commitment for some. Hey, I can operate my equipment and make sure that it complies with the same rules the FCC mandates for hams. I can operate it responsibly. I can operate it courteously . I can use the minimum amount of power necessary for a contact.

Still, is it illegal to operate between 27.405 - 28.000Mhz ? Yes. Is it immoral? A crime against humanity? Absolutely not. To me - speeding in your car is a far more worse crime.

BTW, I do not condone operating on ham bands or intentionally interfering with any service that I am aware of. Yes, I know there are (very few, non essential) services allocated between 27.405 and 28Mhz. I support operations on 27.405 - 27.855 Mhz that follow the same regulations that hams follow.

Hopefully this metaphor can crack the thick skull of the "yes, but it's illegal, yes, but it's illegal, yes, but it's illegal" ham. This is issue isn't black and white.

Bob.

No amount of self justification will erase the simple fact that what you are doing is a crime. That makes you a criminal, and therefore not worthy of respect. You sound like the gang bangers in LA bitching because they are treated like hoodlums.

By the way, I do have a cherry 1974 427 FI ' Vette that I take out to LA County Raceway when I want to speed (it turns low 12's with street tires). When I am driving my Blazer on city streets, I obey the traffic laws. That's what honest people do...

FCC rules mandates amateurs operate on frequencies
authorized by their their class of license. How do you
manage to comply with FCC laws when:
]
1: operating out of band?
2: operating without a license?
3: operating non type accepted equipment?

Actually, there was someone else (who I called the original poster) who
was telling people it was easy to modify a Kenwood HF rig to transmit
DSB who went by the name Skipp and then reamed on me about how long I've
been licensed but wouldn't give me his call when asked, to find out how
long He'd been licensed.

Sure - disdain is a noun. Distain, the word you used, isn't.
And thus the definition of disdain has nothing to do with your
comment to Bill.

A ham by definition does not break the law ... a freebander does

Bob,

Yours is the kind of misunderstanding that, try as people might, just can't seem to be overcome. I know FIRSTHAND that there are agencies that are assigned frequencies above and below the 11 meter CB band. Tell me, what is "unessential" about forest rangers. What is "unessential" about military comms? The difference is the type and duration of commercial and military comms as opposed to civilians who are there just to talk, often as much as possible, to as many people as possible. Business or military comms are short and to the point.

I know the regulars get tired of reading this example, but it is a perfect example of why NOT to "freeband". Some years ago, I was acting as communications officer for Civil Air Patrol on a live search for a light plane that disappeared during a storm. We planned to use a frequency near 11 meters which is a USAF frequency assigned to CAP. Like many rescue agencies, both civilian and military, we use our assigned frequencies so as to separate various kinds of traffic, take advantage of atmospherics (time of day), and keep from "interfering" with ourselves--air to ground on one freq., mobile to base on another, and yet another for "incidental comms" such as flight line, safety, or even sending out for food for the searchers. Another reason for choosing the low power 26 MHZ band was to prevent news hounds, ambulance chasers, and even possibly the family of the pilot from hearing adverse news via scanner. *Most* scanners don't deal too well with SSB. We quickly discovered that there was a "freebander" on that frequency calling, "BREAK, BREAK, skipland", etc with a linear that made it difficult or impossible to use this frequency forcing a lot of incidental traffic onto VHF. I was LIVID! There was NO excuse for this person operating on that frequency whatsoever. He was interfering with an active USAF authorized mission, a real emergency where a life was hanging in the balance. In the following week after the mission was suspended, I began to DF this pirate, determined to put a stop to his outlaw operations. One evening, I happened to be in a nearby town, and absently switched on one of my radios in the car not expecting to hear anything. The guy was pegging my meter and almost busted my speaker. On my way out of town, I made a screeching U-turn and went back into town, stopping at the town PD to ask if they recognized that voice. Yup, they knew the fella and where he lived. I drove to his house and confirmed the location. Outlaw was reported to FCC field office, and was busted for out-of-band operation AND interfering with emergency communications--a serious Federal offense. Betcha he got tired of eating beans from a .10 can!

There IS no excuse for operating on unauthorized frequencies. You might *think* these freqs are unoccupied and that the agencies thereto assigned are "non-essential". That is not for individuals to decide. Just because *you* don't hear anyone doesn't mean they aren't there and that there is no traffic being passed that you could hinder.

Finally, let's say I, or you, rent/lease a piece of property with a nice lake on it. Intending to do a little fishing, you stock that lake with a variety of game fish--bass, crappy, catfish, perch, or whatever. You are busy and don't get out to your lake real often, but one day you decide it would be a good day to go fishing; remember, it's "your" lake by virtue of your lease to use as you see fit within the guidelines of your agreement with the owner. When you arrive, you discover a large group of people on your property, at YOUR lake, catching the fish YOU stocked--in spite of the fact there are No Trespassing signs all over-even right where the trespassers are fishing. I'd be angry and I'd bring charges against each and every one that trespassed on my land. It doesn't make any difference if I don't come to the lake every day, it is STILL property assigned to me by virtue of rent or lease and nobody has any business on it without permission.

"Freebanders" don't have "permission" (license) to operate on frequencies outside the 11 meter band. They are trespassing just as surely as those people I cited in the above paragraph. And when they DO trespass, it pisses off those who are legitimately assigned said frequencies for their exclusive use and it don't make ANY difference if they "visit" (use) their "property" (frequency) once a minute or once a year--the "freebanders" are trespassing just as surely as if they just walked into your/my house uninvited. There is no respect due, and none forthcoming for trespassers, "freebanders", or outlaw radio ops.

Cecil,

If it were YOU on an international flight from London, and an outlaw operator decided to operate on 6.628 MHZ one of the HF aviation frequencies or even a tower frequency of 118.1 MHZ causing your plane to misread instructions, stray into the path of another plane and crash, would that hurt YOU? Of course. Operating on any frequency not assigned to an individual carries the risk of causing loss of lives or property--forest rangers attempting to determine, for example, the direction of a fire's travel in order to evacuate people from its path. US Forest Rangers DO operate above 27 MHZ. Would you want YOUR home destroyed or you life put at risk because somebody thought his hobby was more important than your life? Simply because there was someone with a "leen-yar" covering up fire comms keeping the fire fighters from getting the right instructions?

THAT is the potential harm. That is the reason it is illegal--not because FCC is trying to mess up somebody's fun.

It was a Siemens BFR183W. I also found the model worked better with package parasitics furnished by NEC for their comparable package than the ones furnished by Siemens. More recently, I discovered that Siemens had made some pretty substantial changes in their package parasitic model, and the new ones work much better. I don't know if they've redone the S parameters.

The accuracy of the various models was based on how well the model agreed with actual operation characteristics in a particular application.

Preach it Brother
It could not have been said any better.

FreeBanders are bottom feeding scum.
That should have all their equipment taken away.

In most cases, we aren't.

The most apparent case of damage is when freebanders get above 28MHz.

Gee whiz! When you guys gonna learn to keep your responses short and to the point? Don't write a darn book....nobody reads past the first two paragraphs anyway.
If you can't say it in a few sentences, nobody cares.
Save your editorializing for the New York Times....

A really cheap canned oscillator is probably specified to be
within 100 PPM - or 0.01%. That's fine for adjusting the timebase
on an analog scope, where you're probably aiming for 1% or worse.
If, for some reason, you need better than this, pick up an old
analog cellphone and tear it apart. Inside, you'll likely find a
nice temperature compensated crystal oscillator that's probably
accurate to within a couple PPM.

why do those who break the law always assume that everyone else does also and use that to justify what they do? this argument goes right around in a circle and shows how hypocritical these freebanders are... if you chastise someone by assuming that he is speeding and then tell him to go become a race car driver to do it legally, why don't you get down to work and learn how to be a legal ham so you can speed on the legal ham bands properly instead of slinking around illegally.

What I mean is that the definition of a ham does is not indicative of
breaking the law ... albeit some do. A freebander by definition is breaking
the law when they operate.

So when a freebander is transmitting with legal power levels on the
legal 40 they're still breaking the law?

I'm a CB'er (not for long. I take my written tests early this month),
and I, unfortunately, get sneered at for not having my ticket, simply
because there are those who DO choose to violate FCC rules.

I don't condone violations of FCC rules. However, I would like to see a
sideband only band above channel 40, but below 27.800, with a 50 watt
limit, for CB'ers to DX on... The frequencies allocated for this could
"go around" the currently allocated forestry, etc, frequencies, much in
the same way the CB frequencies skip over the RC freq's.

Just my two cents, here... Of course, your mileage may vary.

No when you transmit of the 40 channels you are authorised to use you are a cb'er. As soon as you turn up the power passed the 4/12 or go outside those channels you are breaking the law

> I'm a CB'er (not for long. I take my written tests early this month),
> and I, unfortunately, get sneered at for not having my ticket, simply

I have no problem with cb'ers ... I was one when I was a kid too ... I do however have problems with people taking what I had to work for.

Why? I regularily work world wide on 10m with as little as 10watts on ssb (min required for the autotuner to work) and that is from the car.

Because most HAM's know how to run their radios, and MOST CB'ers dont. A majority of CB'ers think that turning the modulation up past 100%, using negative peak modulation compression, and other "tricks" makes them louder. In reality, it makes for a noisy band. I know better... My GrantXL, with the 2 watt carrier, at 99% modulation, sounds better than most of the "export" radios in the trucks out there, and "walks" over them as well. Granted, I run a 5/8 dipole on the car (two 4' Wilson Silver Load antennae, over and under), tuned properly, so I'm probably radiating more than they are, but hey, it works.

At any rate, a band for those who do know how to run a radio would be nice... It's a pipe dream... one I won't have to worry about later this month, hopefully, but still.. it would be nice.

There already is one. 10 meters. You just have to get a
license. Whats the point in creating another special band for
people who don't want to get a license? You already have channels
1-40 and it got messed up. So now you've got FRS...It doesn't
make sense to just creating bands for people to use in a manner
inconsistent with the intent. Any unlicensed band is going to be
bedlam. Do you think if the FCC legislated a "freebander band"
from 27.455 to 27.800 that it would be any different? Would the
guys turn off the lean-yars and start using legitimate callsigns?

Uh, 8 feet is not 5/8 wave on 11 meters. A 102" (8-1/2') whip is 1/4 wave,
so a 5/8 wave would be a bit more than 17 feet long.

(you should try a 102" whip, I think you're likely to find it more effective
than the twin four-footers. Because you won't have loading-coil losses.
Mine worked *fantastically* well on 10 meters with a converted SSB CB.)

That isn't freebanding, that is operating on the cb channels legally.

>

Why should there be a need for that? If anyone wants to operate SSB at
50 watts or more and work DX legally, get a ham license.

Try and argue the point all you want, but there will never be any
respect for illegal freebanding except maybe from other illegal
freebanders. If you want respect do something that deserves respect.

These "freeband" morons think that if they listen to a frequency and
they don't hear anyone, it is OK for them to use it. That's why so many
are now moving up to 10 meters. It simply amazes me how anyone can think
that just because they don't hear any communications on a frequency it
must be OK for them to transmit on it. Typical of the cb mentality.

This make me curious. How do you tell how long someone has
been licensed, just from his call sign? If I look up my own
call sign it shows:

Effective: 23 May 2000 Expires: 23 May 2010

But that's only when I was granted a vanity call sign. I have
been license for over 35 years. I thought you could only find
out the latest upgrade, renewal, or callsign allocation.

Oh well, just curious.

Doug:

Hit Wilson's site and read up on what a Wilson Silver Load is....

Better yet, I'll explain it. a 4' Wilson Silver Load is a 5/8 (on 11M)
top loaded coil antenna. Two of them make 1 1/4 wave. Maybe I should
have said 1 1/4 wave dipole?

> channels you are breaking the law

A technicality overlooked by many is that Part 95 operation on 27MHz,
better known as CB, not only sets a maximum legal power level, it also
requires the use of a 'type accepted' transmitter/transceiver. So, even
if you turn the power down on an amateur transceiver and stick the CB
channels, it's still not legal. The law is that CB radios are used on CB.

Not that it functionally makes that much of a difference, but that's the
law.

Dana

Bill:

Apparently I shouldn't have voiced my opinion. With a few taps of your keycaps I've been crammed in with the freebanders. Perhaps I should go out and get an 800W linear, run at 130% modulation, start calling CQ on 28.085 AM, and forget about taking my Tech and General written exams next week?

What do you think?

How is FREEBANDING legal "law abiding" behavior??? Legal operation of a CB
is 4watts AM or 12watts SSB within the frequency ranges of 26.965Mhz thru
27.405Mhz. Any operation above or below those ranges is illegal,
PERIOD!!!!!!!!!!!

> You chose to become a ham because you wanted a little more, and you were

Many more legal bands with the EARNED privileges!!! :)

He chose to
> invoke a basic legal privilege that gives him the satisfaction he wants.

Legal if he isn't freebanding and adhering to above limitations.

> Everybody should be satisfied that they got what they needed in this
> arrangement, but that's not good enough for you.You have to prove your own
> self-worth by dragging him through the mud.

Hmmm..... making a statement like he did in a Ham radio newsgroup??? Gee,
let me guess, he expects also that if he points a gun at a cop, that he
won't get shot either.....

>
> I've been a ham for over 35 years, and I'm proud of that.

Congratulations!!! :) Hope you have taken the time to share your
experience training new hams. We definitely need more properly trained
operators in our ranks...

Most of the people

Bob,
Over the years I've discovered that when someone defends an obviously
illegal activity, they usually have some ulterior motive. What is your
motive?
Do you operate outside the amateur bands?
Why in the world would you defend those who flaunt the laws that make
amateur
radio (and the other radio services) possible?
Steve

I don't know how you extracted that defense out of what I said,
but I have no problem with you voicing your opinion. I just don't
agree with the concept of a special band for illegal operators.
Maybe you were just being sarcastic, I dunno.
I support your studying and taking the exams and upgrading. Thats
very commendable. Check out some antenna theory on the side and
you'll also better understand some of the merchandising
terminology referred to in your other post.
Good luck to you. I hope you accomplish your goals.

Has anybody successfully used the relatively inexpensive Int'l Rectifier HexFet series of devices at the 5 to 15 watt range on 6 or 2 meters? If not IR, are there other inexpensive mosfet devices that you've used?

Good work, Sherlock - you've pointed out it's illegal, *again*. We've established that.

How serious a crime is it? Your assignment - think of all the crimes you can, where does freebanding fit it? Maybe you should go spend your time protesting real crimes (I can provide a list if you need one, where do I start...how about NAFTA).

And, of course you don't speed. You're a decent, upstanding citizen - who turns in your neighbor for digging without a permit - thanks for making the world a better, safer place.

Bob.

The method that I have seen attempted in the past is to look
for harmonic content which maximises when you correctly resolve the
original.

Dan:

I honestly don't know how to respond to this. Your post below is so thick with sarcasm I fail to see your point. Perhaps you could tone it back a few notches and provide some facts (if you can find any) to back up your assertion that (1) I'm a liberal, (2) I'm lazy, (3) that I've operated illegally, and (4) Just what the SAT's have to do with it.

After you've done that, I may consider explaining my reasoning behind my opinion so that you might understand it.

Again, I caution you, do not include me amongst the freebanders; I'm neither one of them, nor do I condone what they do (as I stated in the very first sentence of the quote you so vitriously lambasted.)

So you are telling me theres no such thing as a pile up on a ham band ...
where there may be hundreds of people talking at the same time ? Happens on
them too ... my 10 does fine ... more is irrelevant.

The point I was trying to make, Bill, is this: If the frequencies get "thick" on a particular HAM band, HAMs have a multitude of other frequencies and bands to go to. Not to mention the fact that if the FCC would allocate a sideband-only band in the area I suggested for unlicensed CB, the people running on that band wouldn't be illegals. They would be transmitting in accordance with FCC rules.

> Maybe you were just being sarcastic, I dunno.

Only a little. I suggested the FCC allocate a new band for CB for sideband transmissions. Yes, it would be thick, but it would make the regular 40 less crowded, and give a spot for sidebanders to transmit without (hopefully) being interfered with by AM carriers and the like.

I did not suggest this to help support freebanding; quite the opposite. I suggested it as a way to give those CBers who enjoy transmitting on sideband (like I do) to do so with less interference from the riffraff who run dirty, over-modulated, noise-toy filled, echo-boxed, over-reverb'ed, export trash radios.

That's a pretty good question. Unless I'm missing something, I would
rank it right up there with driving on the shoulder of the road where
such is illegal.

That's pretty good. Or maybe it's like throwing beer bottles and
McDonalds wrappers out the window on the highway, or driving really slow
in the ultrafast lane, or parking in handicapped spaces. Ya know,
something Dennis Leary would sing about.

SSB-
I think I'm giving you the same answer that the FCC would. If you want radio communications as a hobby, get an amateur license. Allocating HF spectrum is an international concern, and really the FCC can't arbitrarily choose to do that. The only reason CB was able to be implemented back in the 50's, is because that spectrum was taken away from hams. The intent was "personal communications" for small business or those who had personal needs, and had no other good two-way radio option at the time. It never was intended to be a band for radio hobbyists and AFAIK, the FCC still looks at it that way.
They gave up trying to license operators on the Citizens Band many years ago, which to a lot of minds, was like throwing their hands up at the problem...and future concerns. To dodge the fact that their 27 Mhz creation became hopelessly useless for what it was intended for, they set up FRS to continue giving back the desired basic two-way service to the public.
I don't think they would be interested in cycling backwards. They have a place for hobbyists, and they have a place for 'personal business' communications. Nothing more is justifiable.

SSB,

I'm not arguing with your points here, but there is something that many
people are not aware of. Quite a bit of that spectrum, either above or
below, is not within FCC's power to give or even regulate--except in
the cases of unlicensed operators. Much of those areas are under
an agency called NTIA--National Telecommunications Information Agency.
They have more "pull" than FCC, and that spectrum is mainly under their
jurisdiction. NTIA assigns and regulates US Gov't frequencies includ-
ing US Forestry, and military, for example. The remainder IS assigned
to forest products and various state forestry/fire agencies. IOW, there
is no spectrum for FCC to give because what areas they do control are
assigned, the rest isn't theirs to "give". I hope that sheds light on
your proposal.

No, by definition this is not "free banding". There is no "legal" anything
if freebanding. If you are operating properly as a CB'er on the allocated
frequencies using authorized equipment and power levels, your not breaking
the law.

If your asking if your only a criminal while operating in the "free band",
I would ask is a person only a bank robber while committing the act, or are
they still a bank robber afterwards?

Yeah, they are call Ham Radio Bands, and all they need is a Ham Radio License like the one your getting. If CBers want to shoot skip, then let them get a license too. I doubt you had any big problem getting your license. The written exams up to a General are easy, and for those who want H.F. the 5 wpm code test is a reasonable speed until the requirement is eliminated.

What you propose to do is if the FCC can't enforce the rules, then heck, lets just make it legal, just like the folks who want to legalize drugs. The only problem with that is where does it stop? Today 26.965 -27.405, tomorrow 26.965 - 27.800, ? 26.965 -29.700, 12m - 10m, ..., you get the idea. 8-))

The short answer is that like most HT's it's unlikely it does. I certainly never found any option to drop the gain or horror of horrors increase it on an FT-50RD, and while it might be a nice item to have, not even commercial HTs have that option.

There is a major difference between something that is simply
unsightly, and something that is dangerous.

Freebanding is closer to the example of driving on the shoulder of the
road...or the wrong way on a one-way street....or driving without a
license...than it is to littering.

If you don't think it has caused problems, look at virtually ALL of
the HF amateur bands and many commercial bands. The free-band idiots
have ruined commercial services above and below 27 MHz, and are now
working on all other frequencies. It ranges from 160 meters up into
the two-way land mobile bands.

This is where enforcement come in. What we need to do, is catch a few
of them and fine them. If we find a few who fail to comply after
repeated warnings, we need to send them to jail. If that fails, we
need to execute them...and if that fails, we need to force them to
live with N1IR for a week. Eventually they will get the message.

So you're saying that its up to each individual to decide which laws they
should obay?
If you can't see a problem with that then a jail cell is probably going to
be your next place of residence.

You live in town but you purchased 20 acres of land out in the boonies with the idea of maybe moving there when you retire in the future. I come along and see your land and I don't see a house or anyone using the land. I observe this for a short while and come to the conclusion that no one is using this land. So I build a little shack there, plant my garden, run a cow or two. Is that OK with you? Don't I have a right to do that? After all, you aren't using it. Maybe I am doing something illegal, but after all, why should you object, you aren't using the land and I am apparently hurting no one and there are others committing much more horrendous crimes. Maybe instead of coming out and trying to get me off your land that you aren't using, you should spend you time protesting real crimes.

As Charlie Brown would say, "good grief". There is always someone who spouts this to try to compare the ham bands to cb. Have you listened to such and such band, such and such frequency? No one argues that there are morons on the ham bands who act like cbers and on certain frequencies you can find them, but on 99.99 percent of the other frequencies you find hams obeying the rules and engaging in courteous communication. Even with the few morons on the ham bands, there is no comparison between ham radio and cb. It's like comparing apples to a sewer pit.

Fact is, it wasn't cross-posted to r.r.a.homebrew, it started
in r.r.a.homebrew. You are right that it has nothing to do
with r.r.a.homebrew, but this is a unmoderated NG and you just
have to learn to ignore some of the postings. Somewhere down
the line, one of the participants in this discussion decided to
include a few other NGs.

El Presidente has announced that he intends to split the INS into
two agencies - one that deals with immigration and naturalization
paperwork and the other that does enforcement (the Border Patrol).

Those of us in FCC field enforcement have advocated that sort
of split for the FCC for decades. Once freed from the "who gets
a license and which non-technical rules apply to whom" political
mess (which is the only "FCC" that The Congress can comprehend),
real enforcement can be done when the technical standards and
enforcement functions and people are absorbed into NTIA which has
scads of funds. The Canadians did that several years back when the
functions of the Ministry of Communications were split between
Industry Canada (the equivalentof the Department of Commerce, home
of NTIA) and the Canadian Radio and Television Commission (CRTC).

Hey, Richard Burton in Southern Cal has been prosecuted six
times, spent time in jail three times, and still operates on
ham radio without a license whenever he gets out.

When is HE going to learn?

Well, true, but since the FCC quit renewing licenses automatically
whenever a change was sent in, you can get some idea if someone was
licensed within the last few years anyways. My point when I asked him
for his callsign was really to find out if he actually had one and since
he never replied, I'll assume not.

I read enough. Lets step back in time (and even before mine). The 27MHz band once was part of the ham bands and was taken from that service to create and "inexpensive business band" for small mom & pop type of businesses who could not afford to undergo the expense of professional 2-way providors. Remember that a lot (and I agree not all) of the operators on that band did operate illegally as it was not intended to be a means of casual communications between ANY owner of CB equipment but between units of the same license. The reason the casual communications between any owners of CB equipment is more or less legal today at all is because it was easier for the FCC to change the rules than lock up 1/3 the country (OK so that may be exagerating considerably) and because the manufactures had (financial) influence to allow it.

The free banders have absolutely NOTHING in common with me. I submitted for legal testing in front of the FCC to obtain my license and I could still pass any code test the FCC ever had. In addition to that my technical tests were not primarily centered around operating practices but on technical topics many of which are not even considered by todays operators (of any service). Granted there were many ex-CBers who have moved into the ham ranks and I helped train many of them while associated with my old ham club. Those I do applaud for taking INITIATIVE in finding a way to operate in a fashion they wanted leagally.

One last word and I am off this soapbox. My 13 year old daughter can handle a 5 speed with the best of them (on private property) but do you think I should turn her loose on public highways simply because she does not want to wait until she can get a license? I din't think so any more than you think we should allow rampant unlicensed hand gun ownership (I know not quite the same topic but hey it too is not legal). The point is - If you are not inside the law I don't have any respect for you.

I am off my soapbox now - WB8FEQ - licensed continuously for 32 years since the age of 14 and proud of it.!

Did you not suggest a band be set aside just for the illegal idiots? They
you should be able to figure out my response.

The SATs having to do with it is....the lowering of the bar. The reduction
of standards to accomidate some person and/or group that is unable, too
ignorant, or just STUPID. See my point?

Also there ALREADY exists plenty of places to work DX and have fun. Its
called Amateur Radio. Unfortunatly without a valid callsign you will be
attacked much worse than here.

That's exactly the way it is. Everyone decides which laws they should obey.
Lot's of people decide to obey them all assuming they know about them all.
Some people decide that they shouldn't obey the speed laws. Have you
ever driven faster than the speed limit? I personally don't like and
rarely wear a seat belt even though it is illegal to do so. Technically,
I am also in violation of the Texas motorcycle helmet law.

You picked a bad analogy. A person did just that on some land in my
home county of Madison in Texas. Nobody noticed him living there.
After N number of years he was discovered. The case went to court
and the trespasser was awarded the property under the Texas homestead
laws. So you better keep an eye on your property or some homesteader
will wind up owning it. Homesteading is a good description of what the
freebanders have done between the CB band and the ham band. Time was
when amateur radio operators homesteaded the radio frequencies.

The problem with your logic is you are using land that is being used.
Freebanders are screwing things up for licensed services, and have
been for years.

They are just to stupid or uneducated to understand that.

Sorta like the mentality that thinks it is OK to "borrow" things, like
someone's property or land, without asking because "they aren't using
it".

I don't know which series you're talking about, however, looking through the specs of a couple IRF HEXFETs I've got on hand, the IRF530 (N channel) and IRF9530 (P channel) have rise times (typical) of 22ns [IRF530, Vdd = 50V, Id = 9A] and 52ns [IRF9530, Vdd = -50V, Id = -12A]. Given this, I would doubt that they would work much above 20-25MHz. If these are the series of HEXFETs you're talking about, I've experienced that they work much better for about 5MHz and down--i.e. power switching devices.

Your milage may vary, but not much.
Good evening.

The logic of my post, I assumed I could "borrow" the property without
asking because it was apparent that "they aren't using it".

I picked a good analogy, I have no right to use his property just
because I observe it does not appear to be in use by the owner.

Borrowing something that isn't yours without asking the owner is
called "theft", but I guess we all have different morals.

Take a listen to ten meters, and tell me freebanders haven't cause a
big problem. Not only have they driven legitiment users off the
commercial areas around 27 MHz, and ruiened things for the R/C people
who used to use adjacent-to-CB channel frequencies, they are now
ruining ten meters.

They are also spreading to all other frequencies in the HF spectrum.

2847. A potential new band for CB'ers? [Was: Re: Respect For Freebanders]

Dan:

Well, apparently you missed the point; or is it that you choose to ignore it? Either way, your attitude towards me on this is a bit disconcerting. I'll state this again just in case it didn't get through the first time" I'm not a freebander, nor do I encourage ANYONE to violate FCC rules.

I'm sorry to hear about your mood disorder.

The point was this: Set aside another band for sideband transmissions only, to help alleviate some of the congestion on CM (they have no other place to go), and perhaps the encroachment on 10M frequencies would tone down; perhaps those frequencies between 27.405 and 28.000 that are allocated to other services won't be interfered with people calling CQ, and perhaps sideband operators on CB's won't get interfered with as much by AM carriers.

I'm not proposing a reduction in standards. Personally, I feel when the FCC removed the licensing requirement from CB they made a BIG mistake. I'm proposing a broadening of bandwidth to help alleviate the congestion on CB that causes people who don't know any better to venture onto the HAM bands and interfere with licensed operators. If the bands weren't so congested, CB'ers might not feel the need to run an amp, because they'd be able to make contacts on much less power.

If you're so shortsighted that you don't see the potential good this could do, then I'm sorry you feel that way.

Will some idiots out there still run illegal power? Probably. Will people who don't know any better still venture out onto bands and frequencies where they don't belong? Probably. Unfortunately, without a licensing requirement, the lack of knowledge by CB'ers helps cause this problem.

This is just my opinion. Your mileage may vary

So you're saying that HAMs are licensed to operate between 27.405 and
28.000? Wow! When did that happen? News to me. ::grimace::

> I doubt you had any big problem getting your
> license. The written exams up to a General are easy, and for those who want

Actually, I don't have my license yet. I go for my written tests next
week. I've been studying code for over two years (see the other thread:
Ticket test suggestions for more info on this) without much result. I
won't go into that rigmarole again here. It's already in that other
thread.

>

That's a bit reactionary, Leland. I don't think legalizing drugs is an
option. I don't see the connection between the two.

I'm proposing additional bandwidth for a particular mode of operation in
order to help alleviate some of the congestion on an already overtaxed
and overused band, which may just help to reduce the encroachment by
unlicensed radio operators on HAM bands.

Someone transmitting with legal power levels on the legal 40 are not
breaking the law they are also not freebanding. They are operating in a
proper and legal manner as prescribed in the regulations. Any other
operation is illegal without FCC/NTIA authorization. No more no less.

One of the objectives of the creation of the GMRS Class D (i.e. Citizens Band) radio service was to provide low cost licensed radio communications for small businesses and family communications. This service was to be limited to 50 miles from the transmitting station and to a maximum power input of 5 watts. This was later changed to, I believe, 3 watts output. Modulation started out as AM phone only and changed to include SSB. For a special channel to be assigned which allows the use of more than 3/5 watts would be in violation of this principle.

Additional comment:

Will a tester come out to an invalid's house in order to test them? If not, how would someone who cannot leave the house get tested to attain their license?

I've heard the "if you want to DX and run power, get a license" argument ad nauseum. Some people are incapable of passing a code test due to dyslexia or other disorders. Some people are incapable of even leaving their house. How do those people attain their license?

No. Two 5/8 wave loaded antenna's do not make a 1 1/4 wave dipole. They
make a dipole composed of two 5/8 wave loaded antenna's. This
configuration will not make a truly efficient antenna. Read up on
collinear antenna's and dipole antenna's. You will see that what you
have is nothing. However for you sake I do hope it works to your
satisfaction. I prefer something else...

This is a classic case of "adverse possession", a gem of
Anglo-American real property law. After X number of years of
use of the property without the owner objecting or otherwise
attempting to oust them, the user gains ownership of the
property. The number of years varies from state to state, and
there's a bunch of loopholes if the owner is unable to inspect
the property for a number of reasons.

"Homesteading" is something else, starting with lawful
occupancy.

In Anglo-American common law, theft requires an intent on the
part of the thief to deprive the rightful owner of the
property in question. If there's no such intent, it's called
misappropriation or unlawful possession.

Don't know about other states, but in Texas you have every right
to use property that does not appear to be in use by the owner.
If you use it long enough, it legally belongs to you.

Exactly, my "borrowing" would be nothing more than theft. Just like the freebanders "steal" what they called unused frequencies. It is beyond me how they can expect anyone to have respect for what they do..

Yep, freebanders (illegal operators) have intruded into the 10 meter band, and other frequencies, and are causing problems. I on occasion have caught an illegal operator on 10 and when challenged often the response is, "well, we didn't hear anyone on this channel so what does it hurt?" Typical of my analogy... no one is using it so I guess I have a right to take it.

"Close" only counts in hand grenades and horseshoes.

The maximum distance figure was (and for all intents and
purposes still is) 150 miles.

The transmitter power was originally defined as 5 watts DC
input (AM). This was later redefined to 4 watts carrier
output (AM), 12 watts PEP (SSB). No change for all intents
and purposes.

The answer is yes. Even back when the tests were only given
at FCC examination points, special arrangements were always
made for folks who could not travel or who were blind or
partially deaf.

I just finished my amplifier. I built it for 40m only. It runs
about 800w input and about 450 rf out on cw. By the way,
don't mistake these for the 6MJ6, which is used in (I think)
a Dentron sweep tube amp. Also, I have mostly Sylvania
and can match them for you is you want. I have a large
enough qty to get good matches.

If you really want to know the answer. Yes the Examiners will be more
than happy to go to an invalids house to administer an Amateur exam.
This is what amateur radio is also about. Helping anyone become a Ham.
Ham's will even go to the invalid's house and give them instruction in
order to gain the knowledge needed to pass the tests and become Ham's.
I should qualify the above to state that I would require the invalid to
be a long term invalid and not just have a cold.

What you are saying Sideband is You are asking for a band that is set aside
for SSB only use, between certain freqs And you think this might help the
congestion, well this band already exists(27.405-27.999)and people are using
hundreds of watts with rules and regulations already in place and they are
not respected and are ignored, They already have this band yet they still
come on 10m. What will be any different then. We should be thankful the FCC
hasn't pulled the plug on 11m it is more trouble than what its worth. One
day they will cut their losses and axe 11m.

Be careful how seriously you take claims on an antenna manufacturer's site. The major ham magazine QST no longer accepts claims of antenna gain in advertising, as there were too many attempts to compare apples & oranges.

We may have a difference in definitions.

In amateur radio, loading coils don't count when explaining how long an antenna is. It's the whip that actually does the radiating; loading coils serve to make the impedance of the antenna reasonably close to 50 ohms resistive, to keep the transmitter happy. (an important function certainly, but a very different one from that of the whip. If you redesigned the transmitter and feedline to accomodate the non-resonant load, the loading coil would be completely unnecessary and the antenna would radiate exactly as well and in the same directions.)

Amateurs often use 5/8 wavelength antennas for the 2-meter VHF band. 5/8 of a wavelength at 2 meters is approximately 125cm, or roughly 50". I just measured the one on my truck, it's 47" long. (well within the tolerance of my non-calculator-enhanced math!) There is a coil in the bottom of the antenna, but its sole purpose is to match the antenna to the transmitter.

Sorry, but in Texas if the owner is paying the taxes on the property, it doesn't matter if he never uses it, it still belongs to him and no one can claim ownership by just using it. I have some pasture land in west Texas that hasn't been used in some years, but I pay the taxes on it every year. You go and try to use it and claim it as yours and see how far you get. If however I fail to pay the taxes for a period of time and you come along and pay the taxes for a number of years (I don't off hand recall just how many years are required), then you may have claim.

Can I move next door to you and operate an illegal CB radio with an old 250 watt tube linear? After about a week of hearing me on your television, stereo, telephone, and who knows what else, I doubt you will consider it such a minor problem. But, don't get excited, I'm only going to be your neighbor for the rest of your life (or until you're forced to move).

And don't think for a moment you're going to filter your equipment to get rid of the problem - my over modulated radio, and my old tube type linear, are so dirty it will take a dozen filters just to cut some of the problem on your television (after that you can worry about all the other stuff you own). Besides, don't waste your effort - a friend has a 600 watt tube type linear that I want and it is in even worse shape then the one I have now.

Cecil, only a person who has never lived next door to one of these "freebanders," or a person running an illegal setup himself, would attempt to minimize the problem like you did above. Since I don't believe you're running an illegal setup, I can only assume that you've never lived next door to one of these fools.

If they're using the same radio they use to "freeband" with, yes.
The radio is either not approved for CB use or has been illegally
modified to operate outside the CB frequencies.

And what are you going to do with all of the users those frequencies
are already assigned to? I've seen a list of government frequencies
(especially military) and there is very little free space available
between the CB band and the 10-meter ham band. They all seem to be
special use (used under specific circumstances), but they are assigned
none the less.

You really are "out of the know". Do you really think Freebanding CBers are getting smarter and they are all spreading out over the entire HF band? 99% don't even know anything other than "40 below" and "40 above". HF? Multiband antennas? Yeah right.

Most of the interference I hear on HF is cause by spanish speaking stations from Central and South America. I have no problem working around interference, with DSP and my highly tuned directional antennas. Perhaps you should upgrade from that G5RV and maybe come up with some ways to deal with interference, you know try to advance the technology or your operating skills. Nahhh....I would rather listen to you bitch on this newsgroup.

Bob.

Sideband, since Dan was talking about your suggestion of a new band for "freebanders," I think he was referring to "freebanders" when he said "a bunch of LAZY illegal fools." Since you insist you're not a "freebander," why would you get so offended by that? And he said you "must" be a liberal, not that you "are" a liberal. There is a slight difference.

Take the chip off your shoulder and you might not be so offended by what others are saying. You've raised a touchy issue in the ham radio community, so you should not be overly surprised that you're hearing a lot of strong opinions on the matter.

Hear! Hear! I've listened to 20 meters many times and have never
heard anything close to the garbage I hear all the time on the local
CB frequencies. I have the obligatory CB radio in my SUV and I'm
actually embarrassed to even turn it on while passengers are in the
vehicle. Even the worst of ham radio does not compare to CB.

The bottom line here is that "freebanders" are running illegally. No ifs, no ands, and no buts about it. Illegal is just that....illegal. Now go take on the day.

> -SSB

For what it is worth, in my VE days in Wausau WI I went up to Merrill to administer an exam to a housebound man who for reasons known only unto him wanted DXCC before he died. I and my partners read an Extra to a blind man after a regular testing session in Wisconsin Rapids at about -35 degrees costing me a few bucks to get moving again.

I have a friend of many years standing who tried to learn code as both a left and right-handed activity at the same time and ran into a brutal 'hump' at about 6wpm. We had to literally tie his left hand in his belt, pump code into the right ear only, and such things to get him to do it only one way. As he holds an Advanced, it must have worked. This is not dyslexia by any means but 5wpm can be worked around.

I have long advocated the eventual outlawing of AM on CB freqs simply because it is nitro in the hands of children. To do this, it would seem that setting up a truckers band (FM, PL, the whole enchilada) to prevent these 'opinion leaders' into ownership mode instead of wandering farther afield would make sense. Adding a sideband segment might fit into this. Marine freqs are also plagued by this sort of thing. The early phone companies did not view pointless babbling and time wasting as valid activities either and lived to regret it. If your point is that we are making the same mistake I tend to agree.

Some years ago a university I happened to be attending built a new library. They installed a few paved paths in obvious places to get to it and waited a few years to pave the paths the students made. This was a simple and practical approach as opposed to putting them in right away and planting landmines to keep the students on the paths. As Flaubert, a French poobah, once said of taxation, the object of plucking a goose is maximum feathers with minimum hissing.

I didn't know this went on. Kudos to you, Dick. Highly commendable.

And I'm still trying to work around it, only my "hump" is right at about
2 WPM.

Actually, Dick, you just reminded me of this precise point, which I had wanted to make, yet had forgotten to.

AM is a volatile emission mode, IMHO. Of course, FM isn't much better; if the deviation is turned up too high, it "bleeds over" just as badly as over modulation and carrier instabilities bleed over on AM. I prefer sideband for a multitude of reasons. This is one of them.

If you're speaking of Calvin College, in Grand Rapids, MI, I attended the same School. Escher started this trend when the school was designed and first built, in keeping with his ideals of letting his buildings flow with nature as much as possible.

>
> Dick Nï¿½BK

Basically, CB needs to be revamped. CB'ers need to be educated about what's "loud" and what causes interference, what "gets out" and what bleeds over. Modes need to change, and bandwidth needs to be reallocated. Leave 1-40 for the AM'ers, and set aside a band for FM and a band for SSB either above 40 or below 1. There are some unallocated frequencies there, I'm sure. I DO NOT want to make HAMs give up any more bandwidth, and I don't want to take seldom used emergency frequencies from other services, but the whole of 27.405-27.800 can't be allocated.... at least I've never seen a chart that shows anything allocated in that area. (Maybe someone has a URL to a chart/page that lists all allocated frequencies?)

I regularily do simplex on the bike from more than that with a 2m ht with 1/2 watt out ... big deal. I drive to the fiancee's place 50miles from where I sit and chit chat back and forth with my father on 10m with 10w output on ssb ... so what? I use a 1/4 wave antenna mounted on the trunk of my car ...

Hi!

I need some help with a strange transistor found in an Atlas 210x
amateur radio transmitter.
It's printed with "CTC CD2545" does anyone know a referring type or
where to obtain this transistor?

Thank you.

Andreas Weller [DM2PAW]

Ten emeters is already ruined, for the most part. There are SSB
operators and truck drivers all over the low end.

It is happening on 160 meters through ten meters, and even in the
two-way land mobile bands.

We don't need to reduce code requirements, or expand bands. The idiots
operating "freeband" are taking care of it all on their own. They have
no respect for anyone else, and demand we accept them and respect them
for ruining whatever frquencies they choose. And the SSB ops are the
worse of the lot.

What a joke.

What a laugh. You think a DSP filter will remove SSB or AM from over
CW?

Get a clue about how filters work.

A narrow signal can be removed from a wide one without affecting the
wide signal much, so a very strong CW signal can be removed from a
weak SSB signal with little ill effect on the SSB . The converse is
not true.

As for your "higly directive antennas" that doesn't work unless the
direction of the signals is quite diferent.

The point is the free banders are causing problems, and it is getting
worse year by year. Most people who operate HF legally, especially CW,
know that.

BTW, what is you callsign?

CTC are (or at least WERE) a significant manuf of SOE HF/VHF/UHF power
transistors. They shouldn't be too hard to locate if they still
exist.

What gave you the idea that I consider it a minor problem? I don't consider illegally driving on the shoulder of the road to be a minor problem, do you? Bicyclists can die because of that problem. Do you care about the RF emissions of freebanders more than the lives of bicyclists?

> Cecil, only a person who has never lived next door to one of these

On a scale of crimes, is freebanding a minimum offense compared to rape and murder? If you shoot the freebander, who would be in the worst trouble? I am not attempting to minimize the problem, Dwight. I am attempting to put it in perspective.

Seems you are the one who has minimized the problem of people illegally driving on the shoulders of roads, putting bicyclists' lives at risk.

Hi Andreas

I have this listed as an MRF450

Specified 12.5V 30Mhz 50W 11db gain

Vceo 20V
Vcbo 40V
Vebo 4.0 V
Ic 7.5 A
Pd 115 W
Cob 200pF
Hfe 10

Hope this helps

Regards

at http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1233594412

I also have several more of these CheckMate CMR400M (dual) magnetic credit card and check readers. They have serial interfaces. They were removed from service, working, when a Builders Square store closed, last year. See picture and description at the above URL. I also have the handheld laser bar-code scanners.

These might be fun for a hobbyist, or for parts, or, could be used in a retail point-of-sale application.

Price is negotiable, but VERY cheap! And I take Paypal, plus M.O, personal checks, et al.

I also have lots of good used Tektronix and HP (and other) TEST EQUIPMENT for sale, at:

http://www.fullnet.com/u/tomg/gooteesu.htm

(Check my ebay feedback comments, through the URL at the top, and you'll know I'm good...)

Thanks!

I see you say you don't support a position, then go on to do just that. In anycase this will be my last on this one......you can not reward outlaw behavior by giving them more frequencies.

Based on the obvious dis-regard and dis-respect for regulations, already in effect, I see no possibility that the rag tag bunch you refere to would obey any new ones.

End of discussion.

The real killer in my opinion is the extremely high, and voltage
variable, capacitances, especially for low Rds(on) devices. These are
very hard to deal with at high frequencies. If nothing else, you end up
eating a lot of power in the driver stage trying to pump charge in and
out of the input C. I have a rig using the IRF510 (Ciss = 180 pF,
Rds(on) = 0.54 ohms) in class C at 15 meters, and it's hard to drive at
that frequency. If I had to make a 6 or 2 meter transmitter with a
HEXFET, I'd probably resign myself to having a high voltage supply. Then
I could use one of the higher voltage devices that have high Rds(on) but
lower C.

The high capacitances, incidentally, are the main reason for the slow
rise times in the rise time test circuit.

It's difficult enough to get them working at HF. I remember seeing
a design for a 6M amp using VN66 fets. I think it was in RadCom.

Yeah, I know what you mean there.

To a point true, but I think you get my drift however. Until somebody makes a stand and says "NO MORE" they will just keep taking what is not theirs to take.

> I'm proposing additional bandwidth for a particular mode of operation in
> order to help alleviate some of the congestion on an already overtaxed
> and overused band, which may just help to reduce the encroachment by
> unlicensed radio operators on HAM bands.

You have to stop and think about the mechanics a little bit. If a new band was created, as you suggest, then there will appear commercial rigs to operate on the new band. Once that happens then hordes of other CBers, looking for a clear channel to talk on, will show up over running the operators there now. Now we have the same situation all over again. SSB operators looking for the open band. They have to learn to be happy with what they already "legally" have.

Ham Radio is not going to be any different either once you get your ticket. Sometimes the bands get crowed so you either put up with it, move, or turn the rig off. We don't just spin the VFO knob looking for an open frequency outside of our legal bands like the freebanders currently do on 11m. Hams seem to have much more respect for their privileges than freeband CBers do. I think Hams have more sense of respect for others rights to radio spectrum than the freebanders do. If there is any spectrum use disagreement it is taken up with the FCC, and let them decide. Hams don't just "occupy" spectrum outside of our bands because we feel we have a "right" to it.

That might hold only if I know you are there and don't protest or make
an effort to have you removed. If you are using the land without my
knowledge, and you have made no effort to contact me, not only will I
retain the property but your improvements as well.

Yeah, I knew that, sort of. One of those things that sits in the back of my mind, coming out every once in a while at embarassing moments.

Incidentally, I've gotten the power amp that I was designing to work properly. I originally was using the IRF530, with Vdd at 50V and I was still having power gain issues even at 13.5MHz. I've still got a lot to learn in regards to mosfet applications, but that was a really nice learning project. The device, using several different values for an output coupling capacitor, seemed to have peak gains right around 2.5MHz. I tried 2 or 3 of them, so I'm 60% sure that they all will operate something like that.

But they sure are nice high-current switches.

A 2 watt carrier? do you just sit there and throw dead keys or do you talk.
If you do talk I am sure it is more than 2 watts so your deadkey figure is
irrelavent.

Not looking for a medal. VEs are required to make reasonable accomodation
to disabilities and medical conditions. Besides, we are generally pretty
good people with a streak of insanity for volunteering.

****

****
Might I suggest Morse Academy from http://ah0a.org. If you have a problem
recognizing sounds the freq can be adjusted as well as the spacing. If you
type decently, learn the code typing. Seven lessons, tried and true
software, read the instructions before installing. Buy a cheap set of cans
from Walmart before those near and dear berate you strongly about the head
and shoulders with large cudgels to stop the incessant beeping.

****
FM has the advantage of being receiver-dependent. Pump 15 kHz deviation
into a receiver expecting five and all you get is 'What did you say?'

Considering that 28-29.7 is a treaty ham band as is the 24.89-24.99 band,
the Commission could not give you them if they wanted to.

The 25-30 range are garbage frequencies to begin with so even the allocated
ones are probably never used. If they are used, it is with hardware that
probably takes three minutes for the tubes to lite and the dynamotor to come
up to speed. It is damned hard to tell just how vital these were and at one
time the FCC was going to a 99-channel CB and clearing everything up toe
27.99. There is no great way to tell. Below CB is also a land mobile
allocation. Hard to tell just what is there. The 11 meter broadcast band
has some STLs in it, one of which plays reggae to keep the freebanders away.
You should remember, however, that while the treaty definition of land
mobile is pretty broad, it really does not include hobbyists.

This thread has identified problems broader than the one you proposed
originally:

Equipment: So long as equipment that is within a pair of dykes of
out-of-band operation is allowed to come thru the ports we are dead in the
water. These things can be made more bullet-proof than they are and whether
intended for CB or 2 meter amateur or marine VHF they need to be. Time to
get Customs involved. Engineering firms can be hired to do the grunt work
just as they are for everything else; the FCC (properly) does no grunt work.

Enforcement: Phil Kane, as usual, makes a good point with respect to separating the enforcement and technical from the political. The priorities and funding are just too different.

History: It is not 1958 but some of the uses of the garbage band predate CB. There is a lot of history to wade thru. I agree fully that Ancient Modulation needs to be kept in the 40 until it dies. While it is an interesting nostagia trip, there is no good reason for ham gear to be AM-capable; another equipment problem.

Attitude: This is a tough one. While I tend to like to legalize facts on the ground to try to get people in the tent pissing out rather than outside the tent pissing in (TNX LBJ) the two good objections are the rewarding of outlawry and the lack of a guarantee that this will stop the problem. In this case, justice lies on the side of the truckers who are for the most part the English speakers on 28.085. There is a real use for a trucking service, it does meet the treaty requirements, and it could be designed to use the present antennas etc on an increasingly electronically-cluttered cab. As they are pretty much the 'opinion leaders' in CB circles giving them ownership interest in a band that was hard to bootleg (13.2 channel spacing for example and PL required) might ultimately help cool things down.

There is less justification for opening a new SSB-only hobbyist service on say 5kHz USB channels simply because you don't fit any reasonable definition of Land Mobile. This is the reason for the skip limits in the regs to begin with and the requirement in a number of countries that at least one party to a conversation be literally mobile. I tend to favor it only because it would accelerate the scrapping of Antique Modulation and the TVI, non-Linears, etc that go with it.

Download the CW software, use my e-mail (God, I love ATT) if need be, and let's get you on the ham bands before the spots go down

Richard:

Thanks for the kind words... You've brought up a few points that I hadn't thought of, and that I need to give some thought to before responding..

I take my written Tech and General tests on the 8th. I'm going to work on my code with KC8HEZ and others here in Livingston county on 2M when I get my set up. Once I get the code down, I'll take the code test, find an HF set, and hopefully be talking on HF by the end of the year.

The next problem is going to be an antenna here in the apt. I've thought of throwing out a longwire and using a tuner, trying to use the gutters on the building as a large loop antenna with a tuner, and a few other options. The 2M setup shouldn't be too difficult. I do have a rail outside my window I can mount an antenna to... I just hope it's high enough to get to the repeater.

Hopefully, by the 10th, I'll have a callsign to send you guys... and by the 15th I should have the domain name corresponding to that callsign.. I'm going to put a site up here at the house for those who are curious.

73's and Hopefully I'll be chatting with you all on the air soon.

I'm starting out taking the Tech and General written tests. Code will
come later this year, hopefully. I'm going to need a 2M set to start,
and an HF set later, once I've passed the code requirement.

I did get that, Leland.. But honestly, the problem with CB'ers venturing
out where they don't belong is twofold: (1) There just isn't enough
bandwidth for CB. and (2) Export Radios that do too much. I think we can
both agree on these two, so I won't go into it too deeply here.

No, but you can look for an open frequency within the bands HAMs are
allowed to transmit on. That's my point... HAMs have the bandwidth.
CB'ers don't. So when a CB'er goes off to find an empty frequency to
talk on, they're in violation of FCC rules when they go outside of the
standard-40. HAMs have MUCH more bandwidth with which to search for an
"open channel"...

I've turned down the carrier on my Grant XL to 2 watts. The radio swings to 5 on AM, and does 0-12 on SSB. the AM measurements are RMS, the SSB measurements are PEP.

I must have missed that part - I don't remember any mention of
bicyclists. All I remember is a mention about driving on the side of
the road, which is indeed minor (unless you hit a bicyclist).

Well, that is certainly stating the obvious.

>that frequency.

How would these HEXFETs behave in a common gate circuit ?

After all, 180 pF at 21 MHz corresponds to a 40 ohm capacitive
reactance in parallel with the quite low input impedance of a CG
stage. Even at 50 MHz, this reactance would be about 15 ohms.

Old VHF tube amplifiers used push pull configurations so that the
stray capacitances of the tubes were in series, thus representing a
smaller detuning capacitance to the input and output tuned circuits,
compared to using two tubes in parallel, in which case, these
capacitances would be in parallel.

Would there be similar advantages of using grounded gate hexfets in
push pull for VHF ?

Good luck with your tests, and welcome to ham radio! As far as antennas go, they are always a challenge in an apartment setting, but you can get creative and will learn much in the process!

Don't forget about going mobile if you are not able to get satisfactory performance with your base antennas or have RF interference problems with your neighbors. I have lots of fun with a Yaesu FT-100D and Hamsticks.

2917. The new 40m band?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-05 13:21:57 UTC
From: Schatzie <jdwalton@home.com>
Message-ID: <V7TI6.15885$K5.2022093@news1.rdc1.nj.home.com>
Source record: 52813

Is it true that the FCC is proposing lopping off the top of the 40m band, but adding 100kHz to the bottom. So says the ARRL in this morning's mail:

==>7 MHZ "REALIGNMENT" AMONG WRC-2003 ADVISORY COMMITTEE PRELIMINARY VIEWS

The FCC's World Radiocommunication Conference 2003 Advisory Committee has approved several "preliminary views"--or PVs--on expected WRC-03 agenda items. Among these is a US preliminary view supporting a realigned 40-meter amateur allocation at 6900-7200 kHz on a worldwide primary basis. The FCC is soliciting public comment on all preliminary views by May 9.

This will come as a blow to all us boatanchor types.

2918. Re: The new 40m band?

I don't know if this is just a silly rumor or if we are gong to get a band realignment... but ... how is this going to wreck boat anchor enthusiasts. Boat anchors I have seen and used will tune way outside the bands. Remember OO's?

Are they proposing a rule against tubes? A rule against multipliers? How would they enforce rules like that? If your boat anchor won't tune the new 100 khz for some reason just build yourself an accessory to take it there. You likely needed a new accessory added on to get onto the "warc" bands when we got those.

I can't be certain, but I think that this was additive to the existing 7000-7100 worldwide allocation. I didn't see where it would lop of the existing 40 meters for the North America's.

The contention seemed to be the European Broadcasters. If the worldwide allocation was the same as ours, those broadcasters would have to move.

Really? Why?

As you may know, radio amateurs in Region 1 countries has only
7000-7100 available for use. It has been a goal for a long time
to have a 40m band of more than 100kHz available *globally*.
The initial wish was to allocate 7000-7300, but this has showed
as being too difficult to accomplish, due to the heavy use of parts
of this segment by the broadcasting service.

In region 1, 7100-7300 is allocated to the broadcasting service,
while 6765-7000 is allocated to the fixed (primary) and the land
mobile (sec.) service. I guess it is far easier to relocate
existing users here than in the broadcasting service.

I think we should all be thankful to the IARU and its partners
in legislation and member organization that this issue is now up
for the conference in 2003. It would seem like we have a fair
chance of finally getting a 300kHz band at 7MHz available
globally.

--Magne / la1bfa

PS: You will have adequate time to re-tune your boat-anchor. I
guess that it will take 5-15 years to implement this band change.

Yes but what you are saying is you are heard with a 2 watt carrier. It is irrelavent what your carrier power is when you are talking. If you had a 10 watt carrier and when you talk it went back to 5 watts then all you are doing is 5 watts not 10.

well, if a 2 watt carrier is full quieting 20 miles away, then the
antenna must be doing its job, wouldn't you think?

Full quieting is normally associated with FM use. Who cares and what does
it really mean you have a 2 watt carrier, unless you go around deadkeying
and never say anything . your carrier power is a useless figure. What is
your carrier power on ssb?

Not really. How about 4 million + miles per watt ?

(Full quieting? Then you must have been using FM emissions, an illegal mode
on 11 meters. :>)

Should creat an interesting market for mod. articles and new dial scales. My
NC 303 for one doesn't tune much below 7.000 (maybe 5khz). I have less
problems with mods than with competing with swbc and ssb below 7100.

You will have a far easier time retuning linear boat
anchor radios to cover the bands. Some rigs will need
a simple retweaking, others will need new mixer crystals,
etc.

Pity the rest of us using more modern gear, where
bandpass filters and programming rules the coverage.
I dread the day when I have to modify my JRC NSD515
to cover below 7 MHz.

Basically the FCC is trying to save some of the 40 meter band. The countries
around the world want to chop off the 7.1-7.3 region 2 allocation to SWBC.
I doubt if the FCC proposal will fly and region 2 hams will be left with only
7.0 to 7.1. Maybe in 10 years the HF bands will be abandoned by government
SWBC in favor of the internet and portable satellite receivers that are
coming on the market and hams will get a lot more spectrum.
Right now the governments around the world use HF for wide area broadcasting
and they want more spectrum. The cost of running dozens of HF transmitters
compared to a couple of satellite channels should go down over the next few
years and it will be economical to use satellites for broadcasting, if
satellite receivers become less expensive.
The Government and religious SWBC have gained more and more spectrum to
broadcast their propaganda while ham radio is losing ground.

Well, there's been SWBC a plenty forever from 7.1 to 7.3 and if we can
convert this inconvenience to some additional freqs, then I'm all for
it. The pirates in the 6.9 spectrum will just have to go elsewhere.
Its a boatanchor dilemma, and if you haven't clipped those diodes in
your rice-box already, it may be time to do so. I, for one, wouldn't
object to band-expansion/shifting based on that reason.
Remember expanding the 20 SSB band below 14.2? Moving the 80 and 40
Novice Band? Adding 10 and 18 Mcs? Lotsa whining, but they were all
good moves.

I find this talk of moving equipment interesting, since the worriers
seem to have no sense of history.

There was a time when "mods" were not about clipping diodes to enable
something the manufacturer put in place. Somebody had a piece of
equipment, it didn't do quite what they wanted, so they modified it,
and then shared what they'd done in the ham magazines. Who knows
how many actually copied the idea, but I would hope the articles
gave other people ideas for something they needed with the equipment
they had.

I can picture an article by someone who wanted to get on six meters
without spending any money. He modified his existing HF transmitter,
a Globe or a Heathkit, probably doubling in the final. He might have
forfeited one of the HF bands, or perhaps the rig dated from the
time when there was an 11M ham band. He had no crystal that would
multiply up to six meters, so he turned to his VFO. It wasn't
intended for VHF (ie, it had not 8MHz range), but he retuned
one of the bands it did tune, just by adjusting a slug tuned
coil. As for the dial, I think he just decided vague was good
enough, and so he never did anything with the dial.

I can picture another article where someone retuned one of those
single-band SSB rigs (they only cover the phone segment of the band,
and the author probably wanted to get the CW segmen). Again,
covering the new frequency only required an adjustment of
a slug-tuned coil. But in that case, he wantes something slicker,
so he went to the trouble of redoing the dial, using rub-on lettering.

Someone once wrote an short article about using their NC300 on
a non-ham frequency; either to get WWV or perhaps to hear
a satellite. He added a trimmer across the tuning capacitor, to
get the new frequency. I think he had an alligator clip and
a bit of wire as a bandswitch.

When the rigs got fancier, and needed a heterodyne crystal
for each of the 500KHz or so band segments, adding a new band
required a new crystal. But most of those old rigs could
cover frequencies close to ham bands without any further adjustment,
and certainly a lot of the receivers could cover most of
the HF range without mods, once the crystal was in place.

Those old articles would be the basis for someone who needed
to get their rig working on this new 40M band, if it happens.
Though, the concept should often be fairly obvious.

It is sad that the ingenuity of days gone by seems to
be lacking in many hams.

Um... Either you're being ignorant, or you're trying to test me...

either way.. my answer is...

DUH!

SSB radio emissions have no carrier.

Um.... Ok...

So I drive a truck.. Big Deal. I have never cophased antennae on my
truck. I find it counterproductive to even attempt to do so.

But if you want to play CB games...

Uh, 10-9 good buddy?

What is really sad is a backhanded slap in the face couched in inuendo,
when a simple "here's what you do" would suffice.
Lets see you make your own tube....

My sentiments exactly. I sympathize with the vintage station guy who
'loses' part of 40 m (if that is indeed the case) on his NC-300. But
geez, any ham who is worth his salt can figure ways around all this.
It may be an affront to vintage rigs, but there's a s**tload of rigs
that won't work all HF bands, or even all freqs...SBE mobiles or
whatever. If the powers that be are willing to give us a cleaner slice
of spectrum, whining certainly serves no purpose. I'll willingly GIVE
them 7.2 to 7.3 in exchange for 6.9 to 7.0. Thats a no-brainer.

For the life of me I don't understand why the countries of the world are so sold on shortwave broadcasting. Technology has advanced to the point where direct satellite broadcasts could be done cheaply and very effectively. A thousand or so 10 KHz channels around 1 GHz could handle it all. If everything were standardized (channel spacing, FM mode, deviation) then receivers could be mass produced cheaply and the shortwave problems would be solved forever.

That sounds good. The credit for the written elements are good for a year I
think. If you
can find somebody to practice code with that would be great help I'm sure.
Depending on your finances, if your looking to save some money, check out
some of the local Hamfests in your area. The ARRL web site has a list of
them all over the country. A used radio can save you a big chunk of coin.
That's maybe your best bet until you figure out what you want or need in the
way of features in a rig. Once you know that then you are in a better
position to spend some money on a new, or newer, radio knowing it will do
what you want. Also don't let some of the Old Timers on this news group get
under your skin either about anything. Some like to take cheap shots at Tech
Class operators. Regardless of what class license you get, or the code speed
you test at, your a Ham at that point, and don't let anybody tell you
different.

> This will come as a blow to all us boatanchor types.

Hey - the boatanchor types, at most, have a little tweaking to do, and more than likely, they know how to do it. OK, sometimes they may need to be a little creative, as some other posters have pointed out, but many of them had to get at least as creative to get the old beast on the air in the first place.

The real challenge will come for the rice box appliance operators. Anymore these rigs are all computer controlled and very hard to work on. Ever try removing an SOT64 chip? The design of these rigs is such that it would be real hard for the manufacturers to supply an upgrade, as if they would rather do that than sell a new rig. And most of the folks who have them, wouldn't have any idea what to do to change them even if it was a reasonable thing to do.

I'm sure there will be a ton of whining about how this is just another way charlie is trying to help the manufacturers sell more gear, but if there is a way to make the 40 meter band a little less hostile, I'm all for it.

Hey Bill,

The guy didn't ask how to get around a problem tuning new frequencies. He just flat out said that all boat anchor enthusiasts are out of luck.

I did make a tube once just to see if it could be done. It worked (for a couple of minutes). My project was not economically viable even if we count time as worth only 1 cent per hour. It was ugly and messy.

All that said...

If a boat anchor enthusiast is worried about wrecking the resale value of antique equipment then outboard, add-on accessories would be the way to go. An external VFO plugged in to the place where a crystal would go or some similar arrangement. Later boat anchors would only require a crystal change for a new 40 meter band and the user would have to simply know the dial is off by 100 khz (or 2 or whatever). Seems simple enough for anybody capable of getting a ham ticket. Out of band operation isn't so touchy for a swl (who probably already has general coverage).

Source record: 52747

This may seem like a silly question, maybe not. Is there any reason why Ciss, Crss and Coss are listed in datasheets rather than Cgd, Cgs and Cds? It probably has something to do with y parameters or something, I'm sure. Why not list the Cgd, etc. outright? [note: I know that Ciss=Cgs+Cgd, Crss=Cds+Cgd and Crss=Cgd] Is it just some sort of ploy to scare/confuse amateur hobbyists and students?

I know the answer has to be obvious, but I've been known to miss some obvious things.

Thanks for any help.

> where to obtain this transistor?
The ATLAS transistors can be obtained from almost any replacenment
transistor supplier in your part of the country as an NTE317 or from
http://www.rfparts.com as a matched pair of MRF412's for about $48.00 pr. I
just replaced the finals in my two of my ATLAS'es with a pair of MRF412's in
one and a pair of NTE317's in the other last month. The MRF412's were much
cheaper than the NTE's. $48.00 pair to $120 pr. Thus my choice to go to RF
Parts co. for the second pair.

Yep, it will be a challenge to get my JRC twins to
work below 7.0000 on TX, the NSD-515 will require
a bit of rework and parts changes to do so...

The real question I have is whether the CW DX window
will remain in the first 25 kHz just above 7.0000 MHz.
There is no reason that the band plan would have to
remain as it is now... It would seem the status quo
would remain for a number years--with the first new
100kHz of the band almost taking on a WARC band
like aura... opinions?

Dunno 'bout all those other "rice boxes" out there,
but mine was very easily modded.

Receives/Transmits from 1.8 MHz to 30 MHz.

NO problem with new bands/segments.

Seriously though, this re-alignment could be
good if it really resulted in a 300 kHz Amateur
only band. I don't trust the process enough. Maybe
I'm just too suspicious...

Hello,

I need some expert advice please
I've been trying to learn all I can about toroidal power transformers

You see, I'm prototyping a simple audio device that uses a single
12AX7 tube for which I'd like a simple light-duty toroidal power transformer.
I know power transformers can get quite large but available space is tight.
How physically small could this be made?

Primary: 120Vac
Secondary 1: 120Vac at 100mA to 300mA - Plate
Secondary 2: 12Vac at 150mA to 300mA - Filament

The plate winding feeds a Fullwave solid-state diode bridge
with a CRC ripple filter design following.

I would like to wind one myself but I could use some expert advice
on core selection and specs. How many turns would these windings
require and at what guage? What brand of core?
Is there a ready-made unit available with these specs?

Iron Powder or Ferrite? or Coiled Lamination (if I have that right)

I'm on a very tight budget and need to keep my costs down
and for now I only need one

Thank you very much for any advice or suggestions
Please reply via Email rexheb@bellsouth.net

Source record: 52753

Can't wait to get realigned to 6.9 to 7.2 MHz. Most solid state,
general coverage boxes can have a diode removed to make them general
coverage transmit as well. Even the older rigs like my spare TS-520S
should just require one crystal change (100KHz lower) for the 40M band.

I had one of these units in for repair a few years ago; the problem with the intermittent display turned out to be a cold solder joint on the regulator that feeds the display.

Maybe I've got my definitions confused, but isn't full quieting when a
transmitted carrier is strong enough to cover all background noise at
the receiver?

I don't recall ever hearing/being told/reading that Full Quieting
applied only to FM. I could be wrong.

From the IEEE Dictionary: "quieting sensitivity (frequency-modulation receivers) The minimum unmodulated signal input for which the output signal-noise ratio does not exceed a specified limit, under specified conditions."

Note the "unmodulated" requirement which would prohibit this term from being used associated with SSB.

Too many people already have SW receivers. Doesn't matter if it's a
WW2 surplus BA, or a new Grundig whiz-bang box. Either one receives
SW broadcasts just fine. In many countries, many people live in
poverty, so the cost to buy a new receiver would be prohibitive.

So it could apply to an unmodulated AM signal, then? If so, my statement
was correct. If not, I stand corrected. I hope someone will let me know
which it is.

PLEASE CHANGE THE HEADER WHEN CHANGING TOPICS
I opened up several posts today and the topic dicussed had nothing to do
with the header.
AND neither the header or the topic had anything to do with homebrew.

Come on folks - lets respect the Use Group Guide Lines at URL:
http://faqs.jmas.co.jp/FAQs/radio/personal-intro

AND FOR CRIPES SAKES __ CHANGE THE HEADER WHEN YOU CHANGE TOPICS.
I just read one with a header of "freebander" nonsense and it was
discussing FM Quieting!!!

I understand the cost of changeover factor, but if people were to apply that to all facets of life, we'd still be riding horses and using outdoor plumbing. Changes like this can be phased in over a period of years with minimal impact. I see going to microwaves as a clear benefit to all involved - better reception, less interference, little or no fading, smaller antennas - it's well worth doing IMO.

Don't you agree?

That's a big 10-fer good buddy. I'm sure you gets lots of horizontal
gain with a 4-ft-long half-wave antenna. These dumbasses don't even
recognize marketing hype when it's served to them on a silver platter.

I don't see where it's that minor at all. If one of my kids got hurt because of someone driving down the side of the road, I'd hunt them down and slowly kill them. If someone scared them with a near-miss, their car would not be recognizable when I was done with it. In short, nobody screws with my babies, else I become the mother of all mother bears.

Lots of people take driving infractions lightly until someone gets killed. All of a sudden there is a great wailing and gnashing of teeth as everyone wonders what can be done to make our roads safe. For starters, might I suggest taking ALL laws seriously, not just the ones that fit your own personal agenda?

I'm with you, Gene. If you think I said "right down there", you are
mistaken. I ride a bicycle. Vehicles driving on the shoulder are
deadly weapons. What gave you the idea I consider it minor?

seems you are fighting with the windmill.....,
I am pleased it is possible to change email subjects with MS Outlook*,
a similar feature for newsreaders seems to be the only way to avoid
too much stupidity on a thread, but it implies a manual operation

I would agree with you, but often the discussion changes over the
thread, and quite often one make arguments on two different matters in
a single post. If you had changed the subject then, it is possible
that nobody would care to see it

in my experience most of the crowd only bother to read a post when it
has a few replies, if it doesn't get that much, it simply dies because
nobody think it is worth participating - not that I care for the crowd
wishing to have an answer they already have seen mentioned several
times before, but it helps, so it seems important not to make the most
radical arguments too early in the thread, nobody cares to reply.

Better to discuss SWR months after months.... and although you don't
care so much, don't ever mention that the VSWR is higher than 1.2:1 to
your transmitter, the crowd will know you are an "idiot"! hi

Maybe not you personally. Just making a point that while many people
might consider something a very minor violation of the law, it might not
be so minor (and perhaps even for a very good reason) to another person.

Renfred,

I took pity on you and scanned parts of my Kenwood R-2000 manual.

I posted files on my web page at:

http://www.dnai.com/~rexa/R2000/

Here's what I put there:

r2kblk.gif 172712 - block diagram
r2krx.rtf 17297 - rx description (rich text format)
r2krx1.gif 321000 - 1st half rx schematic
r2krx2.gif 314081 - 2nd half rx schematic

The solution is probably in there somewhere. The rtf file has a
couple places where it talks about things splitting along the lines
of your problem.

FS: 140 MHz, 10 MHz BW SAW Filters p/n 851921 (only five pieces
available)

Manufactured by Sawtek, these SAW (surface acoustic wave)
filters feature a center frequency of 140 MHz and a typical
bandwidth of 10.3 MHz at -3 dB. Full specs and S parameters
are available at Sawtek's web site-- look under "stock 140 MHz
filters" for part number 851921.

Small-quantity list price for these NOS filters is approximately
$110.00;
I'm asking $10.00 each for plus $2.00 postage to your QTH. Please
contact me
for more information.

Sideband, I will put a cup out for you since you are begging to be correct about full quieting. Notice Cecils definition, frequency modulation recievers, does this give you enough of a hint- that it is FM only. Do yourself a favor while studying for the ham test don't just memorize the answers actually learn what the question mean. If it was fill in the blanks the ham population would decrease by two fold.

Federally-mandated highway signs are in miles and miles/hour, NOAA gives temperatures in degrees Fahrenheit and atmospheric pressure in inches of mercury, the USDA lists crop exports in bushels, postage is determined by the ounce and pound. Just because (and if) some congressmen with nothing important to do declared a "standard" doesn't make it so. It looks to me like industry has adopted the metric system to a greater extent than the government has.

2986. Re: Toroidal Power Transformer design questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-08 02:18:42 UTC
From: Bob <balbert@cnmnetwork.com>
Message-ID: <OIIJ6.7711$oa2.156258@news6.giganews.com>
Source record: 52783

First, you can buy very cheaply a power transformer to do what you want. It would use E-I laminations most likely, the most economical construction. It will also be very small.

Winding your own is a viable alternative, but why toroidal? Toroid cores are much more difficult to wind, and you will need plenty of turns for the primary. Probably the best core to use would be tape wound, and the best material some sort of magnetically soft iron. I don't know what's available these days; I used to build toroidal power transformers using square loop mateirals but that was a long time ago. You can use those too.

Get catalogs from the companies that make the cores. All the design information will be right there. The power handling capability of a core with a given winding material is proportional to the area of the hole where the windings go. There is no theoretical limit of power for a given core; it's the windings that determine that. If you can use wire of a lower specific resistance than copper, you can handle more power.

The important parameter is the required turns-per-volt to avoid saturating the core. The closer you get to saturation, the more energy wasted. High peak currents will flow if saturation is reached. Once you know the safe number of turns per volt you can compute the number of turns. Once you know those, and the size wire to carry the desired current, you can see if it will fit in the hole. If not, a bigger core is needed. Allow for insulation too; you don't want shorts between turns or windings. Make sure your primary won't saturate the core even at highest expected power line potential, including medium duration transients.

Wire size depends on required current and voltage regulation (due to resistance of the winding). A good number to use is around 500 circular mils wire per Ampere. (You get the circular mils by squaring the wire diameter measured in thousandths of an inch.) Any larger size than calculated is fine of course, as long as it will fit on the core.

You asked a simple question and got the $25 answer.

It is more than "some congressman with nothing to do". In 1893 the US officially adopted definitions of the yard and pound in terms of the meter and kilogram. For more info see:

So, what you're saying is, that congressmen in 1893 had nothing
important to do either? All kidding aside, its amazing the we Americans
can't overcome the reluctance to convert. I remember an effort back in
the 70s? that lasted only a very short time. One crew was putting up
the new highway signs, and another was right behind them re-installing
'old' ones. I wonder if anybody saved any pictures of those? And, I
recall that Canada easily made the transition at that time. Our only
remnant of the effort is that a fifth of booze became 750ml.

But so does FM. True, the noise vs. signal curve is different but it's
still there.

The cited definition does specify FM, but really the concept of "full
quieting" is not at all meaningless on AM. Especially when you consider the
effects of AGC, which will back off receiver gain and take the channel noise
with it.

It's a bit more of a stretch, but really the concept of quieting isn't
completely meaningless for SSB either, again considering AGC effects.

An AM carrier without modulation looks just like an FM carrier without modulation. So it seems to me that "quieting sensitivity" could apply to an AM receiver as well although the term "full quieting" is generally understood to apply to FM.

Ok...

I stand corrected.

Allow me to rephrase what I'd originally stated, then..

My 2 watt AM carrier covered up all the background noise on the other
guy's CB, which was roughly 20 miles away, according to his signal
report.

For Sale: Simpson 260 front panel (New).
This is the front meter panel with all lettering etc on it. It is for
the model 260 that has
the 5kv AC/DC jacks and uses pin jacks for test leads.
Price is $12.00 plus $3.50 to mail.

In your case of hte squatter, you stated that noone had noticed him. The major and important difference here is that freebanders have been noticed and lots of people are raising hell about it. To bring your analogy into line with freebanding, the squatter would have had to hold onto the land for the required number of years through either armed force, or simple civil disobediance, not by not being noticed.

I have never run my CB this way. I do have an echo mic on my GrantXL,
but the echo "volume" is barely cracked open. According to three
different modulation meters, I'm set at 99% modulation.

The fellow I was talking to runs his radio in much the same way. He has
a Cobra 148 (same radio, basically), and has his set similarly.

Any more than 100% modulation is going to sound like crap, and probably
bleed over. I know this, and those CB'ers who know this try to avoid
bleeding over, etc...

Now, if you don't mind, I need a nap before I go down to the testing
center to test for my ticket. Have a nice day, Rob, and I hope "huked on
fonix" continues to help your English grammar. ("there's usefull"? Come
On!)

The freebanders go relatively unnoticed by the FCC and the FCC is
who matters.

And, of course, I never said anything about a half wave antenna, either.

Goes both ways, I guess.

Instead of asking every so often, apparently without success, for these devices, you might want to post about why you need them. If you are repairing something, there might be better reason for getting the same part. But if you are building something fresh, you might try something close but not exactly the same, or use a newer design using a more recent (or at least available) IC amplifier.

Below is my response to a similar post of yours from a year and a half ago. I guess you did read it, since now at least you are specifying that the IC is a differential amplifier.

It's just a simple differential amplifier, with some biasing resistors. It was commonly seen in radio frequency work.

The MC1550P is the original Motorola part. Since Motorola made the HEP line, it's going to be the same thing.

You're not likely to find the device in the catalogs, since it's about thirty years old.

You'll have to understand the circuit, and figure out a suitable replacement, which shouldn't be all that difficult since it's a simple circuit. At worst, you could find an IC with a differential amplifier and no biasing, RCA used to make such items, and bias it externally. That might be the easiest solution if you are trying to replace a faulty IC in an existing circuit.

The RCA CA3028 was fairly similar, and would show up in circuits of the same type. It isn't identical, so it might need a bit of reworking of the circuit, or won't work at all depending on the way the IC is used in the circuit. I don't know if you can get a CA3028 anymore.

There probably were other IC along the same lines that might be adapted to the circuit. Of course, I'm less certain that such a thing could be found nowadays.

If this is to build a circuit in an old book or magazine, you might do well to find a more recent circuit with the same function.

Michael

Actually you can run good sounding audio at more than 100%. This requires a modulation scheme other than you have in your 'CB' set. So this leads me to ask this....how can a meter read 'modulation' in the first place?

I was under the impression that in order to read Peak Power, than one needs a O-scope, one that is calibrated preferably.

Not to mention the fact, that unless you are running class C RF, and class B AF (for AM) then you can NOT ACHIEVE 99% anyway.

Actually we have some metric highway signs on I-19 that extends from the
southern end of Tucson down to the US-Mexican border.

I believe this is to make the illegal aliens feel welcome when they enter the
country. Sorta like G. W. Bush making his weekly radio broadcast in Spanish.

Oh, and another thing, the Border Patrol and Customs people always give the
quantity of drugs seized from these same illegal aliens in "Kilos."

See we really do use the metric system<g>.

Hi Doug,

I've fixed my share of Alpha's in the last few years... if you have a specifict problem, feel free to Email me direct to the address below.

A great source of free manuals (all types) is the boat anchor manual archive, located at:

http://bama.sbc.edu

I know there are some Alpha Manuals on the page, have a look.

cheers and 73's

Whatever happened to the consortium of SW broadcasters that was going to
voluntarily move out of the amateur bandspace?

Sad to say, but Swiss Radio International is terminating North America transmissions on SW and BBC World Service has now announced the same thing in recent days. These don't directly affect the 40m ham band per se, but there seems to be a trend afoot with the availability of internet audio and things like the little Worldspace satellite receivers....look at this for example. Its been up and running in Europe and Africa for quite some time....and the users report excellent results!

Interesting, but in looking over most of the web pages there, I noticed
WorldSpace is being very careful not to disclose its location or ownership.
Anyone know why it is being so secretive?

I'm not pitching them or anything, but this is from that same website
and also from
http://www.worldspace.org/

WorldSpace Foundation is a U.S. based non-profit organization that was
created in 1997 to provide
educational and informational programming to people
in developing regions of the world who are
disadvantaged by illiteracy, poverty or geographic
isolation. The foundation partners with a wide array of
organizations to produce its educational programs
for broadcast on WorldSpace satellites. These
organizations include, non-governmental
organizations (NGOï¿½s), UN agencies, government ministries,
international development groups, universities and
community radio stations. Content on WorldSpace
Foundation channels may include basic education and
information on a variety of development-related
topics, such as health, agriculture, environment,
womenï¿½s issues and civic education. Although WorldSpace
Foundation may on occasion work closely with the
WorldSpace Corporation and its entities, WorldSpace
Foundation is strictly governed by U.S. Internal
Revenue Service (IRS) rules and regulations for tax-exempt
organizations and is not a business unit or
subsidiary of the WorldSpace Corporation.

I'm quite certain they are, but now that you mention it, I can't
come up with a source. It has to be something I picked up in
the early seventies.

My HEP replacement guide from 1974 gives the wrong cross for
the MC1550P, which I know is a differential amplifier because
it's listed in my 1978 Motorola databook. The pinout for the HEP590
is missing from the HEP guide.

My ten year old ECG guide crosses both to the ECG816. There's
no internal diagram for it, but there is for the ECG817 (which
the MC1550P crosses to. That matches the internal circuit
shown in the Motorola databook for the MC1550.

I wasn't feeling like digging through magazines to find
a reference that would directly make the connection between
the two. But I just remembered I have the first issue of
73 that I ever saw handy, and it has an article by the legendary
Bill Hoisington. September 1972, on page 57, he's describing
a tuenable 6M receiver that uses the HEP590. It shows the internal
circuitry of the HEP590, and again, it matches that in the Motorola
databook for the MC1550.

The incomplete junk we remember.

I recently picked up a Boomer 600 amplifier which apparently is intended for the 11 meter market. Has anyone had any luck in converting one of these for use as an HF mobil amp for 75-10 meters SSB? I think the relatively high Q of a mobil antenna should minimize spurious emissions that may be a problem.

My older guide has the MC1550G crossing to the 816. The diagram is
the same as for the 817, except that it shows pin 7 tied to the metal
can.

Source record: 52721

Has anyone played with making a better loop filter for this puppy? Somehow just hanging a cap across the phase detector output just left me cold, and I've already made noisy-signal performance (300 baud FSK) better just by splitting their "R1" and hanging the cap off the middle, so I know it can be improved. Good noise immunity is a priority for this one.

Ideas on input signal conditioning also gratefully considered.

> It's not a well-known fact, but the metric system is the official US
standard.
> It's just never been adopted by industry.
==========
IF the US Government (trough the democratic process) has adopted the metric
system as the official standard, why are manufacturers and suppliers to the
US Government allowed to continue with the supply of goods and services
using the lb , foot/inch ,Fahrenheit units.
When watching CNN and CNBC weather reports it's all in miles/hour and
degrees Fahrenheit.
I feel if ANY government accepts a particular weights and measures system
,its agencies should take the lead in implementing that system , otherwise
such a system will never be accepted/used by the nation at large.

73 Frank , gm0csz.kn6wh@ukrs located in Scotland ,which is (still)
part of the United Kingdom , where the metric system has been accepted (I
believe in the early 70s) . It has been generally accepted and implemented
by industry and all Gov. agencies ,although all road signs are still in
miles .
Petrol must be priced and dispensed in litres.

3026. homebrew lineair amps

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-09 14:26:39 UTC
From: ON4CLN <on4cln@qsl.net>
Message-ID: <zscK6.65347$ii.8240170@afrodite.telenet-ops.be>
Source record: 52723

Dear fellow homebrewers.

I'd like to build a kW PA myself, just for the fun of it. Not for myself, but I found someone who needs one and is willing to pay.
The whole thing is still in the "design phase", being a faint idea in my head...
Now, I have several questions / problems to solve:

1. Final stages
For the actual PA, I'd like to use solid state, simply because I don't know anything about valves/tubes (graduated 3 years ago and this was not part of the program), but I'm quite familiar with bipolar and MOSFET transistors (characteristics, usage, drawbacks...).
I found an off-the shelf homebrew solution at http://www.communication-concepts.com/ => they sell the hardware for Motorola application notes, and have a kit for a 1kW PA (PCB, components and matched pair of power-mosfets). Now, this costs abt 1000US$, of which the finals costing 900US$ for a matched pair of MRF154. This is alotta $$$!!!
Question is: has anyone a cheaper source for these MOSFETS, or maybe a whole other design with other components?

2. RX / TX switchinh
Can anyone help me out for a fast and "built to last" RX / TX switching cuircuit?

3. SWR protection
What circuitry should I use to detect (and protect against?) hi SWR?

4. Experience
I'm sure there are some of you out there who have build one or more PA's.
What should I specificly take care of, or take into consideration?

Any help on schematics, application notes and help is surely appreciated!
Reply via newsgroup is ok, direct to my mailaddress is even better!

Thanks in advance to those who'll reply!
73! Franki - ON4CLN

Very simple. The standard is just the definition of units. It does not mean
those definitions MUST be used in ordinary life. The US has never made the
metric system mandatory, although I have no doubt that day will come.

Don't take it too hard. Some folks simply can't comprehend what it must
be like to drive without constantly paying attention to potential hiding
places for cops rather than the road itself.

They're following the First Commandment of Web Design: ensure your site
provides no possible route for users to actually contact you...
==========
The FCC has metricized to a significant degree. According to our license,
my employer's antenna is 430 meters above average terrain - not 1,410 feet.
Other figures in the broadcast regulations, like the minimum distances
between stations on the same frequency, are also expressed in metric
measures. Admittedly, sometimes converted directly from the old
English-system values. ("289.7km" replacing 180 miles, etc.)

That's not completely correct. I believe that the time limit is about 4 years. If I went and 'established' myself on that land for long enough and no one said anything about it, then while I may have been there illegally in the beginning, I do have a legal right to be there, and the courts in Texas will back me up on it. I'm not sure if it falls under homestead or imminent domain, but it is the law, at least here in Texas. I know of people who have lost several feet off of their property line in this very same manner.

Hi Cliff,

You might research older RTTY detector circuits. I've seen a number of
them using the 2211 in various layouts.

cheers
skipp

I have, and I'm going to keep on doing so, but so far the ones I've found have pretty much used the circuit right out of the data book with only slight (if any) changes. I guess everyone's so happy to see a databook circuit that works right off the bat that they're doing it the honor of leaving it unchanged. :)

It works both ways. Some people can't comprehend the peace of mind
that you have when you don't care where the cops are hiding.

All you have to do is go a little slower then all those other
drivers, that are looking over their sholders for cops, and the
cops won't pay any attention to you. In the end, does it really
matter whether you get there a minute or two before me? If you
get there first, do you win? If so, what do you win?

Suggest you check with a lawyer, it isn't that simple. Homesteading and
imminent domain have nothing to do with it.

(I started this right after you posted the original message, put
it aside, and finally I'm finishing it).

But have you thought about doing the modulation at high level? Instead
of putting the modulator after the oscillator and then amplifying, you
build up your power and then have the modulator feeding the antenna.
You don't have to have a linear amplifier chain that way. Audio
requirements may go up, but that's an easier realm. You
certainly won't need as much audio power as you'd need
in a comparable power AM transmitter.

For some reason, this sort of transmitter has faded. Years ago,
this was what you'd commonly see if there was an article about
a DSB transmitter. You'd see complete transmitters, people turning

finals of CW (and AM) transmitters into balanced modulators, and there'd even be add-ons, where an existing transmitter would feed a home-made external balanced moudlator.

It makes sense to do the modulation at a low level if you are thinking of adding a crystal filter at a later date, but that's hardly likely in this case since your oscillator is on the signal frequency.

You could even do phasing SSB at a high level.

Michael VE2BVW

3047. Re: HexFet Power Amp At VHF????

Source record: 52744

Pretty close- but WA2EBY did get a pair of inexpensive IRF-510's to
run reasonably well up through 10 meters. Output was falling off
rapidly at this point, but his 28V design did manage to output around
40 watts with 1 watt drive at the high end. Interestingly, the
frequency he got peak output at was 10MHz in his design. He told
me he invested quite a lot of time to get it to play this well, and he
does work in the amplifier design area. I doubt it would be worth
trying these little gems on 2 meters, but perhaps they could be
coaxed into working on 6 meters. I wouldn't bet on it, however.
The WA2EBY FET power amp can be seen in Mar+Apr 99 QST
magazine. BTW, the power output over frequency was definitely
not leveled, but this may not be an issue for some hams. His amp
runs from 160 through 10 meters, with a peak power output of
about 75 watts on 30 meters with 1 watt drive. Sure beats bipolars
for some applications. I built one using his PCB layout and it has
worked well for me. BTW this design outputs quite usable power
from a 12V supply, as well. I get about 25 watts for 1 watt drive with
13V on 40m. 73, David K3KY

There are some solid state bipolar transistor amp kits available on
the internet. As I remember, the kits cost around 600-700 USD
at the KW level. For mobile use with heavy duty 12V supply, these
might make sense. It also demonstrates that parts for solid state
power amps are still fairly expensive. There has to be some good
reason why tube amplifiers are not yet extinct, and this is it- the
high cost of silicon at that power level. I would only suggest that
it might be worth the investment of your time and effort to learn
RF power tube technology. There is an almost unbelievable wealth
of parts out there for tube amps, much of it in surplus channels
(= cheap!). I have yet to build a single KW HF amp in solid state.
All of mine have used 'valves' and have been built quite
inexpensively. BTW please note that my argument holds for
building amps with *surplus* tubes and components. If you campare
new parts, the price difference gets fairly small. If price is not an
issue, it stilll might be better to go with tubes, as they can be much
more forgiving of short term overloads due to antenna impedance
missmatch including open and short circuit conditions. Loading
errors that are survivable for tubes can prove instantly fatal for
the output transistors if not properly protected with a 'bullet proof'
protection circuit. I doubt you would be happy to see a 900 USD
pair of RF transistors go up in a little cloud of silicon smoke! :o)
BTW some amplifier tubes are almost as fragile, and require grid
protection circuits. These are almost as easy to destroy as
transistors if they are abused while unprotected. It is always
safest for the beginning designer/builder to stick with glass
envelope power tubes. There are many good available types,
both new and surplus. I like 813's, 4-250A'sand 4-400A's (surplus),
and 3-500Z's (new). Many different similar types are used in Europe.
Good luck and 73, David K3KY

Hey folks,

We have a NEW address for the Allied - Knight Kit Bulletin Board!

The old BBS over at BESEEN.COM was being trashed repeatedly by
annoying Taiwanese spammers with totally off-topic ads.

This new Board lets me delete spam, and al;so ban spammers if they try
to register and use the board. The registration is free and takes like
20 seconds. A small price to pay for getting our privacy back!

Many Knight and Allied enthusiasts are out there. Please forward this
to your friends, and to other Search engines, lists, reflectors, clubs
etc.

So please pass the word. KNIGHT KIT LIVES!

73 de AF4K, Brian

Good, then you know to build a few small PA's first, and get used to
what you are doing before leaping into a high-power PA. A good
education will cover about 10% of the problems you might run into in
the real-world.

The real problems with PA's are things like component current ratings,
"ringing" of waveforms that may cause excessive voltage, harmonic
suppression, and IMD performance.

For example, there are amplifier kits that are sold (illegally for USA
users) using 2SC2879's but they have poor biasing and poor IMD
performance. They are OK in a car, but would be too "dirty" for home
use on big antennas where you signal would be stronger and more
noticable. You wouldn't want a 14 volt amplifier over a few hundered
watts anyway, unless you had no other choice.

You are probably limited to 28 volt or higher devices if you want
decent IMD performance and a reasonable power supply for home use.

>I found an off-the shelf homebrew solution at
>http://www.communication-concepts.com/ => they sell the hardware for
>Motorola application notes, and have a kit for a 1kW PA (PCB, components and

>finals costing 900US$ for a matched pair of MRF154. This is alotta $$$!!!

One problem is these are based on Motorola evaluation kits. These
projects do not always work perfectly, and often require some
additional refinements. So don't depend on such kits being "turn-key"
operation.

I know for a fact the evaluation layout for MRF150's in a 600 watt
amplifier has high voltage transients on the drains of the MRF-150's
because of lead impedances and layout. You might or might not destroy
a few FET's while taming it down.

>Question is: has anyone a cheaper source for these MOSFETS, or maybe a whole
>other design with other components?

If I were just building a first PA, I'd build several QRP PA's first.
Better to learn what to do and what not to do with $10 FET's than $100

FET's.

Tube-type PA's are a lot more forgiving, and can give you some insight
into problems without wasting hundreds of dollars learning on FET's.

>2. RX / TX switchinh
>Can anyone help me out for a fast and "built to last" RX / TX switching
>cuircuit?

Relays are the best choice, and then later you might add PIN diode
switching. I wouldn't try to do it all at once, you'll have too many
big projects with expensive parts if you do!

High power PIN diode switches are difficult at HF because of diode
carrier lifetime and other component problems, not nearly as easy as
VHF and higher switches.

>3. SWR protection
>What circuitry should I use to detect (and protect against?) hi SWR?

That's the easiest task. You just need a fast shutdown circuit and to
design the PA so it can take voltage excesses. If you have a voltage
failure problem, it is virtually impossible to design a shutdown
circuit that will save the PA. So you need to make sure you have some
headroom on the peak voltages you might see with load faults.

A standard directional coupler like used in a SWR bridge and an op-amp
comparator can do the job... if you pay attention to rise time of
voltages and make the system fast. You'll need a fast relay to protect
the PA by removing drive, like a reed relay, and have enough headrooom
the PA can take overvoltage untiul it shuts down. Overcurrent is much
less of a problem.

>4. Experience
>I'm sure there are some of you out there who have build one or more PA's.
>What should I specificly take care of, or take into consideration?

Be prepared to waste a few devices while working out bugs! That's why
I would start small.

Your best bet is to pick up an ARRL Handbook and have a look at the projects inside. If you want a cheaper prebuilt unit, consider buying a used Heathkit VHF watt meter off Ebay.

cheers

I guess I should have said: "Given the rise/fall times, and capacitances, I would doubt these devices work *well* above 20-25MHz." That is to say, I would doubt they work well in a nice linear Class A mode. Higher class operation I could understand, possibly [or in fact, considering the design you mention]. As you mention, a good deal of work had to be done to get the amplifier to work over the range required, as well. The question is, is it worth it?
As I said, your milage may [/will] vary.

echo definately sucks on 11m sideband as well, especially thse jokers who
get their kicks by echoing their roger beeps. I never saw the need for the
modulation toys, I have only ever seen two good reasons for a power mic, one
was a friend of mine who had a really soft voice due to his suffering throat
cancer, and he had his setup on a O-scope and had it set at 100% (or as
close to it as possible) by a local radio sho that is owned by a local HAM,
the other was a friend who had a radio with weak modulation, he had it in
every shop in the tri state area and nobody could trace the problem, so he
had a power mic that he barely cracked open. Other than this, power mics and
modulation kits (connex boards) are a waste and useless for good sounding
radio.

3056. Caddock Non-Inductive resistors?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-10 22:14:08 UTC
From: Douglas Snowden <snowden@peoplepc.com>
Message-ID: <tflpvmreldchfe@corp.supernews.com>
Source record: 52650

I have the Caddock catalog here. Looks like you have to buy a pile
of them minimum. Anyone know where I can get a few TO-220
style 50 ohm 50 to 100 watt non-inductive resistors? I also need
a 15-20 ohm at 20 watt. Guess I could settle for another type
of non-inductive resistor, but these are pretty small.

3057. Icom Sound Card Interface PC Boards

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-11 02:22:15 UTC
From: "Bob Lewis (AA4PB)" <rlewis@staffnet.com>
Message-ID: <tfmj6shkj0ro79@corp.supernews.com>
Source record: 52653

I have a limited number (20) of PC boards for a sound card interface which I designed specifically for the IC-756PRO. It should work fine with any of the Icom rigs (such as the IC761/765) which use the 8 pin DIN ACC(1) connector. The interface contains Rx and Tx audio preamps and isolation transformers. PTT can be keyed via an optical isolated serial port interface or via an internal VOX type circuit which has been designed to work well with the digital modes. All I/O lines are filtered with chokes and bypass capacitors. An on/off switch routes all ACC(1) connections to an identical connector when the interface is turned off. Front panel controls for Rx, Tx, and VOX gain work independent of the rig's volume, mike gain, and vox gain controls. Fits in a standard MicroPack "C" enclosure by Lansing Instruments.

These boards are available at my cost of $21 each plus $1.50 shipping. I can send you a zip file with PDF format schematic and parts list. If you are interested e-mail me directly at: rlewis@staffnet.com

3058. Re: HexFet Power Amp At VHF????

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-11 05:46:44 UTC
From: k3ky@erols.spamnocom
Message-ID: <3afb7326.65334153@news.erols.com>
Source record: 52655

The WA2EBY amp is linear, runs in AB apparently. The idling current
is low, about 20mA. This is no class C amp. I would say that 40 to 75
watts output for 1 watt input over 1.8 to 28MHz is pretty respectable.
Yes, output definitely drops steadily above 21MHz. (Output down to
about 33w at 30MHz) The output powers at 1.8 and about 23MHz
are identical (`57 watts) The power peak is at about 10MHz. (75w).
On air reports on the prototype were good on SSB. Not too shabby for
a couple of 2 dollar hexfets. 73, K3KY
P.S. Class A operation would not be practical with this setup, as it
is definitely 'pushing the envelope' already, to run TO-220
transistors with their poor thermal resistance quite this hard.

It's hard to beat the Globar/Kanthal units (used to be made
by Carborundum, then Cesiwid). I can't tell you about minimum
orders. May be the same problem as with Caddock. The big,
round 100w globar ones will sure take more avg. power, and
will handle overloads better. Of course, they are huge- about
1 inch diameter and 5 inches long. I can't believe it- I walked
by two 50 ohm units at a recent hamfest- twice- and didn't buy
them. The guy was only asking 5.00 each. Jeez! Oh well, my buddy
was cranky because it was a small hamfest and there was not
much equipment there. He was bored. He is a good influence
on me, however, as his faster pace through the flea market
causes me to waste a lot less money on parts that I don't really
need. :o) 73, David K3KY

They are self shielding to a large degree, which helps keep power line hum
out of the low level audio circuits due to magnetic coupling. You will find
this type of power transformer used in high end audio power amplifiers etc.

I had a Class A version built and running a couple of weeks ago, using the 510 and 530 [comparison testing]. They were both hooked up to a big honking heatsink. I was pushing just over 10W directly off of an oscillator...probably about 18dB of power gain...which roughly about what you were claiming (75W out for 1W in). Guess I missed that 1W drive the first time around. Class AB, in the strictest of definitions, by the way, is not linear. But it's close enough.

Time to find that article...

modified all the available MFJ1270B and MFJ1274 according to the TAPR
notes, and later discovered that this was meant for 300Baud on 10m
(USB receiption) optimization, 2m FM 1200baud optimization was
simpler, think the optimization was particularly for using the TNC2
with open squelch on the RX.

For KAM I used an XR2211 to dcd detector and fed the signal back to
KAM, the same applies for TNC2C-DL and TNC2C-OZ

3071. VHF power amplifier output impedance matching networks

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-11 20:07:38 UTC
From: Adrian Shephard <jadernyj@podvodnik.cz>
Message-ID: <9dhgkblid1@news.inet.tele.dk>
Source record: 52667

Hi all,
I just wanted to ask what are the main(those most usual) impedance matching networks following a VHF (6m,2m) power transistor to match a 50ohm transmission line (coax) and an antenna. Which of those (T, pi or other) do you prefer and ou have experience. If someone can point me out to some web-site or literature, it would be fine. Thank you all for your efforts,
Adry

Has anybody made the 28Mhz to 1296Mhz linear transverter described in the 1989 ARRL handbook on page 32-14?

If so how well does it go and how did you get the designs for the PCBs?

Michael

> SI or some such thing.

Well, there are two different metric ``sets'' that were used in the scientific community. One was the CGS set, or centimeter/gram/second set. I believe this was also called IU. The other set was the SI set, or Systeme Internationale (or some other such french spelling, I know I'm bastardizing it), using kilograms, meters, and seconds.

During my HS years and on into college (1987--1999), all the science classes used the SI system. The sad part, however, was that the math department used english!

Oh well.

Source record: 52672

When I was in college ('75-'79 in the US), we studied the mks (meter-kilogram-second) version. I don't remember regularly using K for temperature, though. I think we used C. I only remember using K for absolute zero in chemistry.

If we could just get one generation started on the metric system, the US could easily convert. Unfortunately, we get so bogged down with comparisons that a true conversion is almost impossible.

Source record: 52677

Hi Cliff;
I used a Linear Technology switched capacitor low pass filter for a fsk project in past.
There was a bit of tuning required, and bad ground was identified as the culprit.
The LTC1062 provided a faster lock with lower ringing than the traditional passive filter.
Exar did have some design data for op amp filters.
We chose to go the switched capacitor filter route as a time saver.

The only problem was the noise from the clock, at 10 times the cut off frequency.
They are worth a shot, just read the ap notes.
LTI application notes #22 covers general use, # 24 covers the use with a 4046 PLL.
The consideration regarding the DC offset may affect initial lock.
I think Digi-Key stocks them, now.

From: Bob Camp <bob@cq.nu>
Message-ID: <F5aL6.8505$ZC6.1149884@news02.optonline.net>
Source record: 52678

Hi Adrian,

I'm assuming you are talking about power amplifiers in the > 20 watt range.

In general you are dealing with very low impedances. If you tear open the typical amp you usually find that the inductive elements are traces on a PC board and the capacitors are fairly high value mica's. In some of the newer stuff they seem to have found ceramic replacements for the mica's but they still are about the same size. Even at VHF you see various transformers wound on ferrite cores.

The circuit topology generally looks like it's in the "other" category. They get designed to match a fairly weird output and input impedance combination. You also need to set up to keep things stable. Large swamping resistors on the input are not at all unusual, FET amps seem to die without them.

A couple of good things to look into in order to get a better idea of what's going on:

Check out the application notes on the manufacturer's web sites, the data's free.
Next time you see a friend with an amp, pull out the screw driver
...
Read up on baluns and un-un's

The basic theory is a bit odd as well. You are not really matching impedances at either the input or the output. You supply the input with the load it needs to keep things stable. You supply the output with the load that it will deliver the most power into. A good analogy is the power company. They do not match the wall socket impedance to your toaster, they deliver the most power they can into the toaster.

Hope this helps

Bob Camp

What would differ if you get into the QRP zone say an output power up to 10 maximally those 20 W. You can get a impedance that would differ not so much say an optimal output impedance of 8 - 20 ohms. how would you match that to a 50 ohm. Using a wideband ferite transformer, or some reactance matching circuits ?
TNX for the answer, Adry

3086. HF PLL design???

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-12 18:09:31 UTC
From: Philip de Cadanet <phil@invest.fsbusiness.co.uk>
Message-ID: <A$zYvHAbxX$6Ew6G@invest.fsbusiness.co.uk>
Source record: 52684

Firstly, I'd be interested if anyone knows of any building block and or evaluation PLL kits on the market.

I am interested in putting together a mono/dual HF band AM transmitter. Rather than being rockbound or building a VFO I decided to look at PLL's.

My thoughts so far:

There does not seem to be any simple old-fashioned synth IC's any more, unless
you can get some of the common types used in CB radios, either from the CB
shops or somewhere like RFParts in California (I forgot the URL). By 'simple' I mean those with parallel programming and without prescalers. Modern synth IC's are always serial-data, almost always with prescalers ahead of the main dividers, and have an on-board crystal osc, but require an
external VCO. The only suitable example in the Farnell catalogue at the moment is a National part for use up to 550MHz, for 4 or 5 quid.

I've no experience of this type of application, but my guess is that it would be unsafe to operate the synth at the Tx freq if there is to be more
than a few watts of RF in the vicinity. Better to synth a higher freq and
mix down against the reference osc, as in many CB radios with 10.24MHz crystal and mixing. Of course, it's also easier to make a VCO to tune 13 -
18MHz than 3 - 8MHz.

The alternatives for the PLL synth are a) use a modern IC with a microprocessor b)use a modern IC with a logic parallel-to-serial converter
c) use logic ICs to make programmable dividers.

I'd be interested in anyone's ideas.

What about Sheldon's DDS3A
http://www.rf-kits.demon.co.uk/run.htm

Kind of pricey but...

I'm not so sure the DDS thing is worth it. A reasonably stable VFO with a display like the K1 seems to be a heck of a lot simpler. Yeah, I would like memories etc., but the price and complexity of DDS has so far deterred me. Nevertheless, I'm going to take a close look at the DDS3 at Dayton this week. I expect Kanga U.S. will be there although I don't se Sheldon's name on the list.

3093. Re: PCB Methods

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-13 07:09:19 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <3afe32c1$0$5842@echo-01.iinet.net.au>
Source record: 52690

I have tried various methods over the years

(1) The Dalo pen seems to give a reasoable result but the tracks can be etched through if you leave them too long

(2) For small circuits/prototypes eg for a dummy load or return loss bridge I sometimes cut out sections to solder to by using a small drill mounted burr. I cut gaps in the solid copper plane and create a pad. The outside of the plane remains GND

(3) I have made quite complex one off circuits using sections of plastic insulating tape. This is somewhat time consuming but quite good results can be achieved
use double sided board - the top layer is ground
plan mechanical layout and cut board to size
clean the board with steel wool
lay out some insulating tape on another piece of hard board
Using a rule and sharp knife cut the tape into small squares for pads and thin strips for tracks
Plan the circuit layout
Place pads on the board using fine forceps to lift each section from the second board and press it down without touching with fingers - use another object such as a roll of tape to do this
Join pads as required with sections of strip - lift and cut a section with forceps and fine wirecutters. Tape sections can overlap
Even ICs can be laid out - best results are achieved if the rule and knife are used to cut out the pads from a single piece of tape placed on the PCB In this case the pad spacing will have to be measured accurately at 0.1 inch for DIP ICs.
Remember to cover the top ground plane layer with tape!
When the layout is complete, etch the board in ferric chloride - heat and agitiate the solution to speed up etching
Wash board and remove tape from board
Drill holes through pads using a suitable small drill eg 0.8 or 1mm HSS - tungsten carbide will break unless in a drill press
Using a larger drill (say 1/4 inch) at low speed, coutersink holes on the top ground plane layer to create insulation from the ground plane (care not to drill through if the drill is sharp)
Clean the board using steel wool until the copper is bright
Spray the board using PCB lacquer
Through Hole components can now be mounted with the top plane being ground. Because of the ground plane, this method works well for RF circuits

(4) Cut board into small sections and using hot glue stick it to a piece of unetched PCB. The glued sections are pads while the PCB is ground plane

(5) Draft a PCB using a layout program such as Easytrax (free) or one the commercial programs (expensive)
It will take a lot of work to get up to speed with the program but this might be worthwhile if you intend to do lot of electronics
You can get the board layout photoplotted at your local PCB house at reasonable cost. If the board is double sided you can use a section of scrap PCB to tape the corresponding photoplots to and place the PCB to be exposed between the photoplots - obviously the plots will
have to be accurately aligned
Using photoresist coated board (again - get yor local PCB house to sell you some) expose the bord to UV light
There are a number of details which have to be correct here
(1) Light source - not all UV sources are suitable due to various wavelengths - I have used a 300W floodlamp (care with eye exposure!!)
(2) Photoplots must be applied tightly to the PCB or edge definition will be poor. I have used a plastic bag around the PCB/photoplots with suction applied to the bag from a vacuum cleaner and a small plastic tube into the bag - it doesnt matter if there is
some leakage
(3) Make sure the photoplots are not reversed
(4) Exposure and Timing is critical.About 1 foot from lamp and 3 minutes works in our setup
(5) make sure the plot is correct for the photoresist - a negative photoresist gives good results and this is standard but positive photoresist is also available

Remove exposed photoresist using a solution of caustic soda - care as th is is corrosive
Etch the board in ferric chloride as before

You will probably have to experiment with any setup
This method gives commercial quality bare copper boards once you get all the details right but is rather tedious

(6) Draft a PCB and get your local PCB house to do a prototype frame. I have got a frame done for AUS$385 which will give me about 6-8 of a small board. For this you will get commercial quality through hole double sided boards with a solder mask

Hope this helps

Philip
I have just about got a DDS solution ready which will give you crystal
stable fully tunable/programmable frequency agility over the HF band.
If you wanted to be really flash you could even produce the AM by digitally
modulating the DDS output!

On impulse I bought a whopping big power tube, an Amperex HF100 tube, at a surplus place for $15.00 thinking I could look up the specs later on. Unfortunately my old tube reference book doesn't have any information on it. Does anyone know--

1) The power output

2) Plate voltage.

3) Filament voltage and current.

for this tube? Any information would be deeply appreciated. Thanks.

Great article, but I question the use of super glue for adhering the pads.
Super glue is notorious for becoming brittle with age. If you want a
long-lasting project, I'd suggest silicone RTV instead. It takes longer to dry
of course, but on the other hand, it is immune to the heat of soldering and
lasts forever.

==========

At a hamfest I bought 2 identical 50 Ohms dummy loads .It is a ceramic package moulded to a metal strip ,make KDI . The actual resistor measures 9 x 6 x 1.5 millimetre . It is moulded to a metal strip of 22 x 9 millimetres which has 2 holes for fixing to a (substancial heatsink).
One connection is a tiny strip of copper , the other connection is the metal strip .

Although not marked as such they are supposed to dissipate up to 150 W ,eg passing a current of 1.7 Ampere On a digital resistance meter with an uncertainty of 2% the resistance measured of both pcs is 50.3 Ohms.The inductance is about 150 microHenry .
Has anybody on this NG come across this type of dummy load ?

Not if you don't want to code a micro. With a micro you will aslo
have to wire in a display and a keypad/rotary control.

I would like to try using a coulpe of of 8 to 1 multiplexors (most
serial
PLLs I have looked into require 17 bits)

3103. Re: PCB Methods-- try hot-melt glue

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-13 16:25:52 UTC
From: Brad Thompson <brad.thompson@valley.net>
Message-ID: <3AFEB590.7A8AEE08@valley.net>
Source record: 52599

Hello--

A while ago, I wrote an article for "73" magazine that discussed using hot-melt glue
as the medium for sticking copper-and-fiberglass pads to a ground plane.

Visit your local hardware store and buy a package of high-strength hot-melt glue sticks.

Use a sharp knife to trim a small flake of glue from the stick.

Place the glue between the ground plane or substrate and the isolated pad you're using.

Solder a component lead to the pad-- the hot-melt glue will hold the pad to the substrate when the glue cools.

More tips: the substrate and underside of the mad must be free from dirt or oil for this method to work.
The pad has a tendency to slide on its liquid hot-glue "bearing" Use a sharp scribe

to hold the pad in place (a third hand helps, too<g>).
Experiment with various substrates-- I've used business cards, plywood, and window glass to fab breadboards.

If anyone's interested, I can offer FS pieces of thin-fiberglass substrate, single-sided
copper laminate suitable for punching with an ordinary hole punch. Please don't hesitate to inquire for details.

73--

I suppose if someone was in love with the complexity of those muxes and all those lines, then adding a shift register to the mix wouldn't be all that bad, but a PIC sure does simplify the whole thing.

I'm not sure I understand what you are thinking about for frequency input. I agree that shaft encoders are bloody expensive, and keypads are operationally annoying, at least for HF. The only other thing I could think of would be BCD switches, which would work just as well for a PIC as not. If you used a common PIC like the 16F84, you wouldn't have any lines left for a display, but you wouldn't need one, either.

I suppose you could use up/down buttons, but then you would need a display for your hardwired circuit as well, and again, it would be an order of magnitude simpler with a PIC.

The only thing which concerns me about going down the DDS route is cost.

However, do let me/us know a little more or drop me a mail direct if you
wish.

Is your design part of a personal project?

I like the idea AM production but to be equally 'flash' I/we, a
colleague and I are looking at any non-iron, high level route as far as
AM modulators go.

That pretty much leaves only Pulse Duration Modulation for which I think
I have collated about every single printed reference ever produced.

I was going to go down this route for dialing up the frequency:

http://www.eastcoastcomms.com/amtrans/am100.html

This is a picture of a low power AM broadcast band transmitter. I
believe it's similar to the Part 15 boxes you have in the US and the
legal RSL units here in the UK.

Date: 2001-05-13 22:15:49 UTC
From: Norm Clanton <nclanton@megalink.net>
Message-ID: <3AFF0794.898B8F16@megalink.net>
Source record: 52606

I've just acquired a Boonton 92C RF Millivoltmeter, but, unfortunately, didn't get a manual with it. It seems to work very well, except that readings (including the zero) on the 3 mV and 100 mV ranges fluctuate. The other ranges seem fine and steady. If anyone has a manual or experience with this instrument, your suggestions would be appreciated. With only two ranges affected, I'd tend to suspect dirty switch contacts, but figured I ought to seek ideas before I start tinkering with it. Thanks.

For what it's worth, my choice would be an analog VFO with a PIC driving a digital display. The thing that would drive me to DDS would be wanting to have memories. The inability to have the PIC directly set the frequency is the major downside to the analog VFO, IMO.

There are plenty of simple, varactor tuned VFO circuits out there. Generally, varactors are cheaper and more available than variable capacitors, and surplus 10 turn pots eliminate the need for complicated gearing schemes. Even if you pay list price for a 10 turn pot, you are still way less than the price of a decent air variable, and you haven't begun to think of some sort of a drive for the cap. Most of the circuits you see on the net are intended for CW - for AM your demands for stability should be quite a bit less demanding. G-QRP does have some interesting circuits for using variable caps that are available in the UK, however.

VFOs are reasonably easy to construct in the 2-5 MHz range, stabilizing them at higher frequencies gets a bit dicey. Common practice is to then mix the VFO with a crystal oscillator in a 602 to get to the operating frequency.

The digital display eliminates the need for an expensive turns counter on the pot, and it's simple and cheap. An LCD display, the PIC, PIC crystal, trimmer, and 5 volt supply in total comes to less than 25 Euro mail order. This has the advantage of actually reading the frequency rather than hoping that everything worked right. This is significantly less than the price of the popular DDS chips. And with a little imagination, the PIC, and the display, can be put to other uses as well.

Take a look at the Elecraft K1 schematic. This has a lot of the stuff you are looking for - 2 bands, precise frequency control, the 2 bands can be whatever you like, all in a relatively low cost radio. The manual, with schematic and circuit description is available online. They did maybe go a little overboard with the PICs, with all the options this low end radio has 4 computers in it! But they do have some ingenious schemes to use the PICs to reduce the parts count. I don't like their LCD choice, I would go for an LCD with a Hitachi controller and more digits, but then, I only need to buy one, not a thousand.

To tell the truth, I've been struggling with this very same question myself. I'm building a 20 meter CW rig, and my initial thought was to have an analog VFO. (In fact, I have the VFO built.) But I would very much like to have

memories, and that spells DDS. I haven't found a reasonably priced DDS lashup that would let me drive the programming, and once I get it built, I now have the issue of phase noise. I don't have enough test gear to really see what I'm doing there, so the problem concerns me. But I'm not interested in a fully blown, all packaged up VFO like Sheldon's because I have a lot of ideas about how the control of the radio should work. I didn't see Sheldon on the list for FDIM, but perhaps the US Kanga guy can help me understand how accessible the programming in the DDS3 is. It's kind of pricey, especially on this side of the pond, but if I could get it to do what I want, maybe it's the thing.

Oh, and I keep saying PICs because they are cheap and easy to program with a simple homebrew programmer. There are lots of other micros out there with other features, but the PIC, especially the 16F84, has gotten real popular for homebrewing.

Anyway, that's my two cents. (hmmm, do they say that's my 2p in the UK?)

Perhaps you continue to view the worlds through broken glasses

Good operators both Amateur and Citizens band operate
within the law and frequencies allocated to them under national laws
and international agreements

The term homebrew means you build it yourself at home
to meet these legal and technical requirements
and the discussions here are supposed to act as an information
exchange to help each of us learn how to do this better by exchanging
ideas and information.....

NOT WAYS TO BREAK THE RULES AND LAWS

In regards to amplifiers being built that would easily exceed the
legal limit if operated at maximum ratings It is somtimes more
prudent to build a device that operates at a fraction of its maximum
design power handeling capability
so as to ensure reliablility when operated continuioulsy for extended
periods of teime ie radio sporting events - and high duty cycle modes
such as RTTY etc.

those amateur radio operators who operate out of band with amateur
equipment are also treated by their peers as no longer worth of
remaining amateur operators and if they do not stop operating
outside of the law they pay the price of loosing their equipment and
priveleges as well as being subjected to fines and jail terms like
any other person who continuiously disregards the laws.

Once you have a varactor-tuned VFO, you have a VCO. It's not *that*
huge of a step from a VCO to a PLL, especially if you already have a
PIC in the circuit.

Remember, a PLL doesn't at all imply the presence of a DDS (they're
two different frequency synthesis schemes).

Once you start mixing to get on-frequency, you *really* ought to reconsider
a PLL scheme. It is usually better to run a VCO at the desired frequency
and employ a down-mixer in the *feedback* loop than mix a VCO up;
by doing any mixing in the feedback loop, image suppression and feedthrough
is much less of an issue.

> The digital display eliminates the need for an expensive turns counter on

And a common PLL chip adds perhaps 5 Euro to that.

> display, can be put to other uses as well.

Well, the accuracy of the display is going to be determined by the accuracy
of the PIC's crystal, which is usually pretty good but, as you imply, requires
trimming when used as a frequency counter.

Again, there's no need to be discussing DDS here at all, a PLL will easily
do the job, especially a dual-loop design. A popular configuration is to use
a PLL to control the 'main' VCO and a DDS to generate a down-mixing
LO, which takes advantage of what a PLL does best and what a DDS does
best.

No, it does not spell DDS. It spells synthesizer, which could easily be
a PLL design; a dual-loop synthesizer can give very good lock-up time
combined with relatively fine tuning steps (how fine is fine enough? 10Hz?).

DDS has the advantage of essentially immediate frequency change (since it
isn't a loop, it doesn't have to lock up) and very fine frequency steps. The
disadvantage is primarily the relatively high spurious noise characteristics
(not technically the same as phase noise) as well as usually high power
consumption.

I'm curious why people don't much talk about dual-loop PLLs any more,
sure, they're a little complicated but they're really pretty straightforward

and have the advantage of fewer high-speed digital signals to generate internal QRM (also an issue with many LCD displays).

Hi RCR,

Still don't know your name and I don't have a call book to hand.

I do appreciate all this feedback and am learning stuff here.

I have had several e-mails privately, not sure why as I find all this
stuff most interesting.

I think DDS is out of the window due to both expense and my not
requiring memories or other bells and whistles.

Following all the various links provided so far has given me a whole
bunch of good reference material. I had not thought of the G-QRP stuff
but am now aware that members have carried out a fair bit of work in
this area in the past.

One US retail outlet are offering LCD's for 3 bucks which is my kind of
price. I would be happy with thumbwheel tuning and wanted to stay away
from keypads as this added to the cost which is paramount or at least
equal to the importance of keeping this whole project simple.

Once again many thanks.

This part of a DSP receiver ultimately - though I doubt I will ever get there! The AD9854 has quadrature outputs which would make it ideal for an I/Q circuit.
The am could be produced by a PWM scheme though I am not sure how you would get rid of the subcarrierr sidebands or conventional amplitude modulation as the output amplitude of the chip can be controlled to 12 bit resolution.

If you want to have a free running VFO look at the VFO PLL stabilizer/frequency readout at my webpage
This was based on a design by Eamon Skelton in Elektor but I used a different micro, had programmable offsets and was automatic (no manual lock).
These boards are available and some 25 have been built (successfully as far as I know!!)

My partner just e-mailed the following back to me and made some valid points which he would like comments to.

By the way in reference to the UK currency, we currently have around 1.45 US dollars to 1 UK pound sterling.

'Thanks for links to the two synth circuits - those would do fine, but you'd be looking for obsolete components. The Motorola oscillator IC would be nice to use if you could find one - someone was advocating its use only last month in RadCom. But my
criterion for choosing components is availability from Farnell. So my oscillator would use BC109's or modern package equivalent, and the big issue would be the varicaps - Farnell do not have a good selection, and oddly the price for the only LF/HF type,
MV1404, is quite unrealistic at 16.15UKP ea, so who's buying those is beyond me - not car radio mfrs, for sure. RS comps have none. I will tap up Micrometrics for some samples of ideal varicaps (http://www.micromet
rics.com/hf.htv.html)'.

> The guys told me they work fine at 200W HF.
> 73 W7ZFB

The MA4P1200 has only a 2 to 4 microsecond carrier lifetime. This is a
little short for the low end of HF. I would suggest a part from their
MA4P4300 series of diodes instead. These have a higher carrier lifetime
(8 uS minimum) and can be used at lower frequencies.

I have not seen my Unitrode PIN Diode Handbook for a while so I cannot look
up the ratings of the UM9401 diode the MaCom diode is supposed to replace.

For those interested in PIN diodes, some excellent reference are given at:

There is a new PLL on the market manufactured by Peregrine Semiconductors; the PE3236 has both serial and parallel programming inputs. The built-in pre-scaler is switchable. It can be used up to 2 Ghz. It is sold worlwide by Richardson Electronics.
I bought 3 and they all work well. It is a good substitute for those Hams familiar with the MC145151P2. I am using it in the parallel mode in a synthesizer from 1 to 2 Ghz. I am also interested in using 3 wire serial control from a PIC and I would be very interested to look at the homebrew programmer mentioned in this thread. Last year, I designed and built a parallel to serial programmer using about 8 CMOS costing 50 cents each. It has 20 switches to enter one fileld for the reference frequency and the same switches are used for the second field which is the F in divider. I built this for experimentation because it is not practical from an operational point of view. I used it with the National LMX2324
PLL which in my opinion is the best PLL for Ham use because it is simple and you do not have to program it for charge pump current and there is no circuitry for fast switching which requires a special external filter at the charge pump output. It has a fixed current value. In the parallel mode, I will use the PE3236 with 2 BCD thumbwheel switches and an EPROM. This will not give me the frequency but I will have 99 channels with a table for conversion to frequency. The LMX2324 (About 4 dollars at NEWARK) and a PIC with frequency display appears to be the most economical and practical way to go. I have never worked yet with PIC's but this thread is motivating me. Regards! VE2AUC

Take a look at this:

http://www.techniks.com/press-n-peel.html

once you "master the process" it works, but it took me some trials to
optimize all parameters...

Philip
I presume you wanted me comment
All the components in the VFO freq counter/stabilizer are easily available
and contemporary - I dont know about Farnell UK. They have a very wide range
in Australia. I would be surprised if any of the components are not
available in UK also.

Hi Richard, and Jos,

I replied to Jos's private e-mail.

>I presume you wanted me comment
>All the components in the VFO freq counter/stabilizer are easily available
>and contemporary - I dont know about Farnell UK. They have a very wide range
>in Australia. I would be surprised if any of the components are not
>available in UK also.
Yes, I had another look at your site and it shows nothing that's
difficult to find.

We still have a fair few component sources over here.

I have hooked up with a couple of large component distributors who also
supply Fair-Rite ferrite products which I need for both the PA and Pulse
Width Modulator sections.

The PA is run in class-D at present and the prototype rig is presently
rock bound on 160m.

The next stage was this PLL.

I am still gathering information.

Regards

Philip G4ZOW

3130. FS: New Eimac 450TH tube

Newsgroup: rec.radio.amateur.homebrew

FS: I have one more 450TH tube (had 3) that is brand new in the factory metal framed (for antishock shipping) box. It is an EIMAC tube (new). I want $85 for this last one. This type of tube has the plate cap on top and the grid cap on the side and it stands about a foot tall and makes a great kilowatt amp. I had a friend that ran one so hard that you could see the grid shadow on the plate as it was white hot and it just kept on running....a very durable tube. If interested call mike at (979) 693-1461 (eves) or email to gspubl@tca.net

Maybe it is time to design the oscillator for a low VHF frequency and
divide it down to the required LF/HF frequency.

At VHF/UHF you might even be able to use a high Q helical resonator or
a 1/4 line resonator to create a low phase noise signal. However,
non-ideal frequency dividers may ruin this advantage.

Yikes, tell me that's 16.15 pence and not 16 pounds Sterling! Most varicaps are around USD $2 this side of the pond. The MV1404 is a little pricey at about $7 (about 10 Euro). But often you can find the popular types (MV209, MV2115) for under a buck.

Source record: 52631

I was thinking about resurrecting my good ol' AEA IsoLoop antenna that's been sitting in the garage for the past few years after the stepper motor died. AEA, of course, has also met it's demise so I'm on my own to locate a new one. I haven't been able to locate the original manufacturer, Applied Motor Products of Scotts Valley CA, on the Web either, so I'm guessing that they also have passed from this cruel world. I don't think I need an exact match, but I haven't been able to locate any suppliers so far. Any suggestions for sources please?

Thank you and 73,
-- Dave, WA0TTN

This coming Sunday....

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday May 20th 2001
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Discounts

A sellers discount season pass is available which
offers a 33% discount. See the advanced registration
form below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all

sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

If the UM9401 will do at the frequency in question (whatever it is), the data
sheet can be found here:

http://www.microsemi.com/datasheets/WT6-37.PDF

A neat PIN diode handbook that will tell you almost everything you need to know
about PIN diode applications can be download here:

http://www.microsemi.com/corporate/products/rf/pinbook.asp

The parts can be found at:

www.rfparts.com

They are $3.95 each.

3138. Re: VHF power amplifier output impedance matching networks

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-16 01:24:45 UTC
From: Bob Camp <bob@cq.nu>
Message-ID: <xFkM6.38009$ZC6.6061627@news02.optonline.net>
Source record: 52634

Hi Adrian,

How you finish up depends on where you start out. The next question would be power supply voltage. After that would come operating mode.

Just as a guess let's say you are running +12 volts and want to run SSB.

If you keep the device 3 volts out of saturation you are running 9 volts peak to peak of signal on the output. Just to keep the math simple let's call it 3 volts RMS.

Your ten to twenty watts works out to about 3 to 6 amps RMS at 3 volts. This is roughly a one to one half ohm load. Pretty darn low, but it's linear and broad band.

As another guess let's say that you want to run true class C into a narrow band tuned load (Q > 10 say).

Now you have 18 volts on the device - 6 volts RMS. Your current is 1.5 to 3 amps and the impedance is 2 to 4 ohms. Not quite as low, however now you are restricted to a L/C or tuned line matching setup.

Another way to go would be with a higher supply voltage. Obviously that makes the matching easier.

Hope this helps.

Bob Camp

You must of heard the term 'Rip off Britain'.

Most expensive gas in the developed world, that along with most
everything else including the women.

I would end up buying components in good quantities to make it
worthwhile ordering from abroad in one hit once a design had been
perfected so if you have any other possible suppliers of varicaps on
your side worth checking out?

Ideally would like manufacturers names/URL's so that I can get full data
together inj the first instance.

Many thanks

Phil G4ZOW
